The original discovery of the virtues of many therapeutic substances is surrounded with great interest, and we understand that Mr. Wellcome has given a good deal of attention to that branch of investigation. The collection of a large number of objects of special medical virtue cannot fail to be of value, especially as the bulk of the exhibits will be lent by medical men. The exhibition is meant not for the public but for the profession, and is intended to commemorate the completion of the first quarter of a century's existence of the firm of Burroughs, Wellcome and Co.

#### Action Against Sir Patrick Heron Watson.

THE decision of the second division in Sir Heron Watson's appeal against Lord Kincairney's interlocutor approving of the issues for the trial was given on the 18th inst., and was partially favourable to the appellant. The Court, by a majority of three,

to one, disallowed the first issue—that as to breach of confidentiality in disclosure, during precognition, to a law agent of facts concerning the pursuer. The second issue was allowed—whether the defender stated to the law agent and counsel that the pursuer was bent on inducing premature labour so as to free her from any permanent reminder of her marriage. The case, it may be remembered, arose out of evidence given by Sir Patrick Watson in an action for separation and aliment, the pursuer in this action failing in her case, and subsequently suing Sir Heron Watson on account of evidence given by him in behalf of her husband. Lord Young, who dissented from the remaining judges, thought that there was no relevant case whatever for sending to a jury against Sir Patrick Heron Watson, and that it was only just and fair to state that, so far as his opinion went, nothing which he was alleged to have done or said was at all improper or discreditable to him or any member of his profession. The case involved a principle of great importance, namely, the inviolability of knowledge gained of a patient's affairs. In this instance Sir Patrick Watson was consulted by a wife who was bringing an action for separation against her husband. Sir Patrick gave evidence for the husband, and stated that the wife on the occasion of her visit requested him to perform a certain operation. For this alleged breach of professional secrecy both the wife and her father brought actions against Sir Patrick, claiming £2,500 each damages. The part of the action remaining to be settled is that his statements as to the operation were falsely and calumniously made.

#### PERSONAL.

THE KING has sent the following reply to a letter announcing the death of Dr. Vintras, the late physician to the French Hospital in London:—"Sandringham, November 11th, 1904. Sir,—I have had the honour of submitting your letter to the King, and I am commanded to inform you, in reply, that his Majesty regrets to hear of the loss which the hospital has suffered by the death of Doctor Achille Vintras. I am, Sir, your obedient servant, KNOLLYS. The Secretary, French Hospital in London."

MR. ANTHONY BOWLBY, C.M.G., F.R.C.S., has been appointed to the post of Surgeon to the Household by his Majesty the King, a post rendered vacant by the recent lamented death of Mr. Herbert Allingham.

DR. MITCHELL BRUCE, who has been connected with Charing Cross Hospital and Medical School for the last thirty years, has been elected consulting physician to the hospital on his retirement from the active staff.

DR. J. S. COLLIER, Assistant Physician to the National Hospital, Queen Square, and Dr. E. I. Sprigge, Assistant Physician to the Chest Hospital, Victoria Park, and the Victoria Hospital for Children, have been recently appointed Assistant Physicians to St. George's Hospital.

It is probable that the proposed American memorial to Professor Osler will take the form of a great medical and library building to be erected in Baltimore.

THE inaugural address of the Medical Women's Society, Edinburgh, was given on Friday, November 11th, in the hall of the University Union, by Dr. George A. Gibson, on "The Uses of a Debating Society."

THE KING has been pleased, on the recommendation of the Secretary for Scotland, to appoint Dr. W. Leslie Mackenzie to be medical member of the Local Government Board for Scotland, in room of Dr. Russell, deceased.

THE second biennial dinner of the past and present resident assistants of the Victoria Infirmary was held in Glasgow, on November 11th, under the presidency of Dr. William Dove Macfarlane, Jun., of Busby.

MR. JOHN TWEEDY, President of the Royal College of Surgeons of England, will unveil the memorial window to the late Mr. W. Cadge in Norwich Cathedral on Tuesday next, when a short service will be conducted by the Dean.

IT is interesting to learn that the widow of the late Professor Finsen has been accorded a pension of 3,600 kroner yearly by the unanimous vote of the Danish Parliament on the proposition of the Cultus Minister.

DR. W. F. DEARDEN, a prominent citizen of Manchester, has been placed on the Commission of the Peace of that city. Another medical man has been accorded a similar distinction in the East Riding of Yorkshire in the person of Dr. J. J. Jefferson, of Market Weighton.

DR. WHITELEGGE, C.B., delivered a most interesting inaugural address to the Epidemiological Society on November 18th, upon the subject of the epidemiological aspects of industrial diseases.

DR. E. H. TWEEDY, Senior Medical Officer of the Gold Coast Colony, acts as Cantonment Magistrate of Kumasi in place of Captain T. A. Pamplin Green, who is acting as Commissioner for the North-Western District of Ashanti.

MR. JOHN IRONSIDE, of the Medical Department of the Orange River Colony, has been promoted to the position of Secretary and Registrar of the Medical and Pharmacy Council of that Colony.

DR. J. H. BAIN has been appointed District Surgeon of Richmond, Cape Colony, in place of Dr. David Traill, who has resigned, and Dr. Ludwig Schloss becomes District Surgeon of Bredasdorp.

## Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

#### SCOTLAND.

AGE LIMIT FOR THE STAFF OF THE ROYAL INFIRMARY, EDINBURGH.—Contrary to the general anticipation, the Court of Contributors of the Royal Infirmary last Monday refused to endorse the report of the special committee on this subject, and passed a resolution that an age limit of sixty-five be adopted for all physicians and surgeons, including University Professors. The resolution was moved by Mr. Charles Ritchie, and seconded by Dr. P. H. Maclaren, the members of the committee who dissented from the findings of the majority, as mentioned in this column last week. The Lord Provost, who presided over the meeting of contributors, said he earnestly hoped that the decision of the meeting would make for the benefit of the institution. The managers would loyally carry it out. It is not yet known whether the rule will be applied to those presently holding office as full physicians and surgeons, several of whom have passed the age of sixty-five.

QUATERCENTENARY OF THE ROYAL COLLEGE OF SURGEONS, EDINBURGH.—This ancient Corporation completes the four-hundredth year of its existence in 1905, and for some time back the officials have been preparing for its celebration. The function has been arranged for the 20th and 21st July, when, among other events, a large number of distinguished

members of the profession, both at home and abroad, will be admitted as honorary Fellows. On Thursday the 20th, there is to be divine service in St. Giles Cathedral, followed by a luncheon and an address from the president; thereafter the honorary Fellowships will be granted, and there will be a reception. On the 21st there will be visits to museums and other institutions of medical interest, a garden party, a dinner, and a reception. The sister college and the Corporation of Edinburgh, will also take part in entertaining the College of Surgeons and its guests.

#### BELFAST.

**THE SMALL-POX OUTBREAK.**—During the past week there have been five more cases of small-pox in Belfast, all removed as soon as discovered to the hospital at Purdysburn. Of these five, one is a severe case in an unvaccinated child of eight years, while the other four are all modified by vaccination.

**ULSTER MEDICAL SOCIETY.**—The first of a series of social evenings for the members of the Ulster Medical Society was held in the Medical Institute, Belfast, on Thursday evening, the 17th inst. The President of the Society, Dr. William Calwell, entertained the members and some other medical men to light refreshments, and the social amenities offered by the Institute were enjoyed till a late hour. The Council of the Society intend to issue invitations to a similar evening next month, the idea being to bring the members of the profession, not only in Belfast, but in the surrounding districts, into more intimate social relationship in their leisure time. The Institute forms a common meeting ground for men from all parts and in all classes of work, practice or teaching, and such evenings cannot fail to promote friendship among them.

#### THE DIMINISHING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the letters which you did me the honour of inserting in your pages during the discussion of the above-named subject some weeks ago, I insisted on two main facts—first, that the diminishing birth-rate is due mainly to the practice of preventing conception by artificial means, which already prevails among large sections of every class of the people; and, secondly, that the restriction of the number of children was, in the majority of cases, not prompted by motives of prudence, but was rather the outcome of a narrow form of anti-social egoism which is willing to give up everything in the pursuit of ease, pleasure, and amusement, and looks upon duty, toil, and self-sacrifice as evils at all costs to be avoided. I pointed to France as a living object-lesson in these matters, and ventured to declare that the nations which should follow her example to its logical conclusion were doomed, as she is unless she speedily mend her ways, to destruction. As a lover of my country and a believer in the mighty possibilities for good of a vast dominant Anglo-Saxon empire, I should have been gratified if my views could have been proved false; and I am not at all pleased now to find them receiving the strongest corroboration from what is evidently the highest authority. I refer to the author of a series of special articles on "Infantile Mortality," the last of which appeared in the *Times* of to-day (Wednesday, November 9th). The intrinsic quality of these articles, not excepting their literary style, stamps them as the work of a first-rate man—not an uncommon phenomenon among *Times*' contributors—and I feel a little flattered to find he expresses, although much more forcibly than I could have done, virtually the same conclusions that I had in my letters put forth. The articles deserve your attention, Sir, and that of all students of this truly important question—a question upon which the prosperity and the stability of the Empire rests beyond all others. I will quote only two passages from the last

article; for the facts and arguments upon which they are based the originals must be consulted. Probably they may be published in a permanent form later:—"Although fewer children are born in proportion to population, a larger number of them die soon after birth. What is the explanation of this grave state of things? It might possibly be explained by a general decline in physique, which renders women less capable of child-bearing, so that they have fewer children, and those whom they have are weaker. But the change has been much too rapid and general to permit of that hypothesis, which has no other evidence to support it. Moreover, physical incapacity is not the cause of the declining birth-rate. That is well known to be due to deliberate prevention, which is practised more extensively among the industrial classes than among those above them in the social scale."

"To sum up, the unnatural concurrence of a stationary or increasing infantile mortality with a falling birth-rate, which so seriously threatens the national vitality, finds its true explanation neither in external circumstances nor in the employment of women, but in the habits of the people. Throughout the scale, from mere thoughtlessness to actual murder, the same elements are seen to be at work and to tend, in varying degrees, towards repudiation of the duties of life and their subordination to ease, comfort, pleasure, and self-indulgence."

I am, Sir, yours truly,

A STUDENT OF SOCIOLOGY.

November 9th, 1904.

#### THE SPA TREATMENT OF ARTHRITIS DEFORMANS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have read with great interest the article contained in this week's issue of THE MEDICAL PRESS AND CIRCULAR by Dr. Bowen-Davis on "The Spa Treatment of Arthritis Deformans." While agreeing with him in a great deal of what he says, I am nevertheless inclined to think that he attaches too little importance to the rôle played by rheumatism in its production. Seeing that rheumatism is now almost (if not, indeed, conclusively) proved to be of microbial origin, I would suggest that the various lesions of arthritis deformans, resembling as they do the joint changes observed in Charcot's disease, may be the result of inadequate nerve supply, due to the poisoning of nerve endings by the toxins elaborated in the system by Poynton's micrococcus.

It is noteworthy, as Dr. Bowen-Davis says, that these lesions should be so prone to manifest themselves at the climacteric period, and it may be as well to bear in mind in this connection that the nervous system is at that period of life undergoing profound changes, none the less important that they may not be accompanied by visible changes. From my experience of balneo-therapeutic measures in this class of case I am convinced that they hold out distinct chances of improvement if not of actual recovery.

A point in the history of these cases is worth noting, viz., that if careful inquiry be made a history of weakness long preceding the joint changes may be obtained. In fact, I feel that it is hardly going too far to utilise this symptom when complained of as a means of differentiating between arthritis deformans and chronic rheumatic arthritis. Perhaps Dr. Bowen-Davis may be able to corroborate this observation.

I am, Sir, yours truly,

ARTHUR G. BENNETT.

St. Ann's Hill, Cork, Nov. 18th, 1904.

#### REPORT ON SLEEPING SICKNESS IN THE CONGO.

THE members of the expedition despatched by the Liverpool School of Tropical Medicine have sent to the Committee a long report on their experiences

in the Congo. Dated from Stanley Falls, September 20, the report says:—

"The members of our expedition left Leopoldville on June 23, and reached Stanley Falls on September 15. One of the State's steamers, the *Roi des Belges*, was very kindly placed at our disposal by the Government, and we were thus enabled to make fairly complete observations on the spread and distribution of sleeping sickness along the Congo River from the 'Pool' to the 'Falls,' a distance of nearly 1,000 miles. A disease whose nature had been previously unrecognised occurred among the State's cattle at Coquilhatville, Nouvelle Anvers, and Romee. It was investigated, and its pathogenic agent shown to be a trypanosome, whose species is as yet undetermined. It was considered advisable to communicate the results of this work directly to the Governor-General at Boma, in order that immediate measures might be taken against the disease. It is no exaggeration to say that sleeping sickness is a terrible scourge among, especially, the riverine tribes—who, by the way, are generally totally distinct from the tribes living frequently only ten to thirty minutes' walk from the river banks. From Leopoldville to Bumba cases of sleeping sickness were present in practically every town visited, and the percentage of trypanosome-infected individuals among the general population was high. After Basoko and up the Falls only imported cases (with two exceptions) of sleeping sickness were seen in a few of the towns, and no trypanosomes were found in the general population. The inland towns which were examined, at M'Swata, Tschumbiri, Lisala, and Bumba, showed a much smaller percentage of trypanosome infections than did the corresponding riverine towns, and it was exceedingly rare to see a case of sleeping sickness.

"From our observations and from information which we have collected, it is very apparent that sleeping sickness has spread in the Congo in recent years along the lines of communication—*i.e.*, along the rivers. The spread of the disease has been much assisted by the practice of taking large bodies of natives, soldiers, and labourers, from one part of the Free State to another. For instance, four natives were chosen for gland puncture, because of large lymphatics, from 77 persons examined at Yalembe. Two of these were found to be infected with trypanosomes. Both seemed in robust health. Three years previously one had returned from a year's work as a labourer at Bolobo, where there is much sleeping sickness. The other had spent three years as a labourer on board a steamer plying to infected districts. A third man, suspected of sleeping sickness, was examined and trypanosomes found. He had been ill for two months, and had returned one and a quarter years before from a year's work at Bolobo. We are told that there was a well-marked case of sleeping sickness in the village (absent at the time of our visit) who had also been a Bolobo workman. Yalembe, situated on the river bank, some little distance above Basoko, is in an uninfected area, and the latter two cases are the only instances of sleeping sickness known there. It is only a few months since the transportation of cases of sleeping sickness on State steamers has been forbidden. Individuals previously affected had been allowed to return to die in their, perhaps, uninfected villages. Declared cases of sleeping sickness are easily recognised; but, as we showed in the Gambia, *trypanosoma gambiense* may be present in the blood for months, even years, and the patient remain in apparently perfect health. The importance of the early recognition of such cases is obvious, and it has long been one of our chief aims to devise some easy and fairly accurate method of detecting the presence of trypanosomes. We believe that in 'cervical gland palpation' we have now an excellent clinical method of detecting an infected person. When many of the cervical glands have been enlarged to above 1.5 by 1 cm., other causes being absent, trypanosomes have generally been found in the drop of fluid obtained by aspirating a gland with a hypodermic syringe. As a rule simultaneous examination

of the blood had given a negative result. Cervical glands have been chosen because the native's femoral and inguinal, and, to a less extent, his axillary glands, are usually enlarged. In uninfected areas the cervical glands very rarely reach the size indicated above, and in none of the glands punctured in non-infected areas have trypanosomes been found. Our work in this direction is far from complete, but we believe that it tends to indicate that no intending labourer or recruit, coming from an area in which sleeping sickness exists, should be accepted if he is found on examination, other causes being absent, to have fairly numerous, moderately enlarged cervical glands. The tsetse fly was incessantly present from Stanley Pool to Basoko. These flies were very numerous among the myriads of islands with which the middle Congo is strewn, and frequently came on board our steamer while we were in mid-stream and distant 300 or 500 yards from land. After Basoko was passed there were very few flies, and just after we left the mouth of the Lomami river the last one was seen on the steamer. Although the natives of the towns at which we stopped above Basoko recognised the fly, none were found in the neighbouring bush. There is certainly a marked reduction in the number of tsetse flies above Basoko, and it is possible that there may be stretches of river where none occur. It is an interesting coincidence that where there were many tsetses there was much sleeping sickness. Where these flies were scanty, cases were rarely seen. The common species of tsetse on the middle Congo is *Glossina palpalis*. At Menseme and Nouvelle Anvers this fly frequented the houses of Europeans."

#### METROPOLITAN ASYLUMS BOARD.

AN ordinary meeting of the managers of the Metropolitan Asylum District was held at the offices on the Embankment, Mr. A. C. Scovell presiding. A letter was read from the London County Council stating that the Public Health Committee were desirous of discussing with representatives of the Board "the subject of facilities to medical practitioners and students for acquiring experience of small-pox," and asking the Board to appoint representatives to the conference. The communication was referred to the Hospitals Committee, with power to appoint representatives. The Works Committee reported that the total cost of the erection and fitting up of the Millfield Homes (where accommodation is provided for 100 patients), including the cost of the site, but exclusive of that of furniture, was £25,084, which works out at nearly £251 per bed. The original contract amount was £17,228, but certain unforeseen works were found necessary when the buildings were in progress, which involved additional expenditure. The same committee reported that the total cost on completion of the White Oak School was £119,707, or £5,986 less than the anticipated expenditure of £125,694, for which the Local Government Board issued their order on March 23rd, 1901. On the recommendation of the Hospitals Committee, it was resolved to affix the seal of the Board to certain agreements with the Royal Colleges of Physicians and Surgeons consequent on the decision of the Board to take over from those colleges the work of preparation of anti-toxin serum, which the managers, with the approval of the Local Government Board, have decided to undertake for one year from January 1st next. Dr. G. E. Cartwright Wood was appointed for one year from January 1st next to have charge of the work at his present salary of £400 for the year, with duties, in addition to the preparation of anti-toxin, of general bacteriological work for the Board as might be directed; and Professor G. Sims Woodhead was appointed for the same period as adviser in connection with the Board's work of the preparation of anti-toxin serum at a fee of 100 guineas. Mr. T. Duncombe Mann, the clerk, presented returns showing that there was only one small-pox patient under treatment, and that there had been no admissions to, or discharges from, the Board's small-pox institutions during the fortnight ended Thursday last.

## Obituary.

W. C. NEVILLE, M.D.DUB., F.R.C.P.I.

It is with more than ordinary regret we record the death of Dr. William C. Neville, of Dublin, who died on the 15th inst. After a distinguished course in Trinity College he took his medical degrees in 1878, and soon devoted himself to the obstetric branch of the profession. In this line he had already reached a high place both as a teacher in the old Carmichael School and in practice, when, unfortunately, his health gave way, and he had for some years to retire from practice. During his retirement he gave much time to the study of pathology and bacteriology, with the result that when he resumed more active work a few years ago his opinion as a pathologist, particularly in gynaecological cases, was recognised as one of the best in Dublin. Under the mastership of Dr. Purefoy he was installed as Pathologist to the Rotunda Hospital, and the work he did there has been of the greatest value. In fact, at the time of his death his authority in the special branch of gynaecological pathology was second to none in the kingdom. His work, however, was done so modestly that few outside his own circle of acquaintances knew anything of it. Though ailing for some weeks, he was unaware that there was anything seriously wrong with him and he kept at work until eight days before his death. An acute attack of nephritis proved quickly fatal. A man of wide culture outside his specialty, an athlete of note in his younger days, he once captained the Irish Fifteen. Dr. Neville retained to middle life the freshness and honesty of youth. Of marked literary tastes, and with a literary gift of a very high order, it is unfortunate that circumstances forbade more generous contributions to the literature of science. His name is associated, however, with what is probably the most useful axis-traction midwifery forceps that has been devised. At the time that his health first broke down he had in preparation a work on obstetrics, which, alas! has never been carried to a conclusion; and again at the time of his death he was engaged in writing a contribution on puerperal septic infection to a similar work. He also had in contemplation the preparation of a manual on gynaecological pathology. Had Neville not succumbed in the first instance to the consequence of hard work and mental strain he would long ere this have reached the very topmost rank in his profession. There are many men who can claim pre-eminence in the practical side of the profession of medicine, there are many who have acquired a wide knowledge of theory and who at the same time have the power of placing their knowledge before their fellows; but there is no man with whose work we are familiar who unites the three qualities as did he. A man of absolute honesty and fearlessness of principle, withal of singular gentleness and tractability, with an indescribable charm of manner, Neville's memory will remain green among his friends when many who have figured more largely in the world of medicine have been forgotten.

## Laboratory Notes.

### NEW REMEDIES.

Messrs. PARKER, DAVIS AND COMPANY have sent us samples of the following three new specialties:—

1.—*Acetozone Inhalant* is a powerful germicide, deodorant and local anæsthetic. It is stated to contain 1 per cent. of acetozone dissolved in liquid petroleum, a colourless, odourless, liquid paraffin. The Inhalant is used as a spray from a nebuliser, after the nasal chamber has been thoroughly cleansed with an alkaline solution. The germicidal action takes place only after the acetozone has been hydrolysed by the moisture of the mucous membrane, and thus ensures the therapeutic application of the per-acids whilst these are in the nascent condition.

2.—*Adrenalin Inhalant* is a preparation consisting of a solution 1-1,000 of adrenalin chloride in an aromatic neutral oil base with 3 per cent. of chloroform.

It is an excellent application in inflammatory affections of the nose and throat, and is recommended as a soothing and antiseptic astringent in acute rhinitis or coryza. The best results are obtained by spraying it into the nasal passages from a nebuliser. Of great service in the treatment of hay fever and chronic nasal catarrh, and superior to many other astringent agents because of its bland nature in the treatment of pharyngitis, tonsillitis, and laryngitis with aphonia. Also used as a lubricant for urethral instruments, tending to reduce the turgescence of the mucus by its astringent action.

3.—*Adrenalin Ointment* is compounded of one thousand parts to one part of adrenalin chloride in a bland, unirritating, oleaginous base. It is adapted to the treatment of inflammatory conditions of the mucous membrane of the nose in coryza or rhinitis, hay fever and asthma. It is a useful application to inflamed surfaces such as external and internal hemorrhoids. Put up in collapsible tubes provided with an elongated tip, to facilitate introduction into the nose, urethra, and external ear, and by means of an ointment syringe within the rectum.

### ALLSOPPS LAGER BEER.

SIR A. CAMERON reports that his analysis of the lager beer manufactured by Messrs. Allsopp and Sons gave the following results:—100 parts by weight contain the following percentages: Water, 89.49; absolute alcohol, 4.34; malt sugar, 2.04; Dextrine, 3.34; albumen and albumenoids, 0.40; acids, calculated as acetic, 0.12; and mineral matter (ash), 0.27. It is free from excess of acid, from "preservatives," and from arsenic and other impurities which have sometimes been detected in ales. It is an excellent beverage, and one which persons who cannot drink heavier malt liquors will be likely to find digestible and wholesome. It is brewed on the continental low-fermentation system the fermentation rooms being kept at a uniform temperature all the year round by ammonia ice machines, whilst the method of manufacture in their new lager brewery at Burton-on-Trent is thoroughly up to date.

### Addresses on the Poor-Law Medical Service in Ireland.

DURING the past week Surgeon-General Evatt, who is on tour in Ireland under the auspices of the Irish Medical Association, addressed a series of meetings at the different medical schools in Dublin. The first meeting took place at the Royal College of Surgeons, and at it Sir Lambert Ormsby took the chair; the second meeting in Trinity College, Sir Charles Ball in the chair; and the third at the Catholic University Medical School, Dr. Anthony Roche in the chair. At all three meetings Surgeon-General Evatt's address was received with great enthusiasm. The question is, however, being asked, What is it all for, if the Irish Medical Association are about to abandon the Enniskillen programme, and to withdraw their demand for a minimum salary of £200 per annum? It is not the mere abandonment of the actual sum demanded as Enniskillen that we fear will work harm, so much as the sending abroad of an impression that the members have been beaten on one point and can therefore be also beaten on others.

### The Medical Graduates' College and Polyclinic.

THE sixth annual dinner of the Medical Graduates' College and Polyclinic will be held at the Treadero Restaurant, Piccadilly Circus, on Wednesday, December 7th, at 7.15 for 7.30 p.m., Dr. C. Theodore Williams in the chair. Ladies are admissible as guests. Dinner tickets, 7s. 6d. (exclusive of wine), can be obtained from Mr. Hayward Pinch, F.R.C.S., 42, Chenies Street, W.C., to whom all communications should be addressed.

### St. Louis Exhibition Awards.

BESIDES those already announced in connection with medicine and medical appliances, a gold medal has been awarded to the Jeyes' Sanitary Compounds Company for Cyllin and its preparations. Also to the Hutchinson Acoustic Company, a Gold Medal for the Massacon and Acousticon, as the best appliances known for the relief of deafness and instruction for the dumb.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

### IRISH POOR-LAW MEDICAL SERVICE.

Writing a letter of regret for inability to attend a lecture by Surgeon-General Evans, the Most Rev. Dr. Hoare, Bishop of Ardagh, expresses sympathy with the object of the meeting and with the intention of the Irish Medical Association, and says:—"It is quite wrong to expect professional men to discharge their onerous and responsible duties with credit to themselves and satisfaction to the public, unless a due sense of proportion in the remuneration of their professional services is observed by the people's representatives. No doubt the people are poor, and the demands upon them consequent upon the Local Government Act are well nigh oppressive, but there should be an amelioration of the status of the hardest worked man in existence—the Irish Dispensary and Workhouse Doctor."

**BUXTON (F.G.E.).**—If you will give a little more detail as to the exact current available from the main we should be pleased to advise you as to apparatus.

### THE VAGARIES OF MODERN LOCOMOTION.

LORD Baring's motor-car, which was sent to Winchester in haste last week to fetch Doctor Applebe and a nurse to Stratton Park, to attend on Lord Norbrook, ~~ran into~~ a milk-cart on the return journey. Dr. Applebe and the chauffeur were thrown out, the doctor sustaining a fracture of the left arm, and the chauffeur a dislocation of the shoulder.

**G. A. G. BROWN (Liverpool).**—If you are anxious to secure a resident patient the best course is to write for particulars to the Hon. Sec. Association Resident Patients, 18A Hanover St., London, W.

### A THERAPEUTICAL NOMENCLATURE.

We understand that the two new ships on order for the White Star Line are to be named in accordance with the traditional termination in "ic"—one the "Cathartic" specially recommended for a speedy passage, and the other the "Emetic," more particularly adapted for travellers who desire a quick return.

**MONOPLEGIA (Orkney).**—Whether the conditions be one of neuræmia or of hysteria, it would be wise to try the effect of a course of high-frequency electrical current. The good effect is not usually experienced until the eighth or tenth application. Go to a medical specialist.

## Meetings of the Societies, Lectures, &c.

THURSDAY, NOVEMBER 24th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. G. Henschell: Modern Intra-Gastric Methods in the Treatment of D. cases of the Stomach.

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. S. E. Harris: Cancer of the Rectum.

**SAMARITAN FEMALE HOSPITAL FOR WOMEN** (Marylebone Road, N.W.).—3 p.m. Dr. Roberts: Cases from the Wards.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. F. N. Kelly: Practical Points in the Hygienic Treatment of the Respiratory Affections (illustrated by preparations). (Post-Graduate Course.)

**CHEARING CROSS HOSPITAL.**—3 p.m. Mr. Gibbs: Demonstrations of Surgical Cases. (Post-Graduate Course.)

**THE HOSPITAL FOR SICK CHILDREN** (Great Ormond Street, W.C.).—4 p.m. Lecture:—Mr. S. Collier: Peritoneal Infection in Childhood.

FRIDAY, NOVEMBER 25th.

**CLINICAL SOCIETY OF LONDON** (20 Hanover Square W.).—8.30 p.m. Papers:—Dr. C. E. Box: The Crises of Pustular and Bacterial Meningitis.—Dr. H. D. B. Weston: A Case of Unilateral Tuberculous Meningitis in which a Bulicous Eruption followed Lumbar Puncture.—Mr. E. M. Corner and Mr. L. S. Dodgson: Post-operative Acute Local Tuberculous Infection.—Mr. C. Wallace: A Series of Intussusceptions in Children.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m. Mr. M. Yearsley: Clinique. (Ear.)

**POST-GRADUATE COLLEGE** (West London Hospital, Hammersmith Road, W.).—5 p.m. Mr. Armour: Injuries to the Spine and Spinal Cord.

**NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC** (Queens Square, Bloomsbury, W.C.).—8.30 p.m. Dr. J. Taylor: Ophthalmoplegia in Diseases of the Nervous System.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture:—Mr. P. Brooks: Amblyopia, Congenital and Acquired.

MONDAY, NOVEMBER 29th.

**ODONTOLOGICAL SOCIETY OF GREAT BRITAIN** (20 Hanover Square, W.).—8 p.m. Papers by:—Mr. T. H. Kell-ock, M.D., M.A., F.R.C.S., on "Antinomycosis," Mr. E. Denison Pedley, F.R.C.S. Ed., M.R.C.S., L.D.S. Eng., on "The Relationship between Dental and other Diseases."

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital).—4.30 p.m. Lecture: Dr. Corner: Maula and Melanconcha.

## Vacancies.

**Bermondsey Parish.**—First Assistant Medical Officer. Salary £17 per annum, together with ration, washing, f. furnished apartments, and attendance. Applications to K. Pitts Fenton, Clerk, Guardians' office, 183, Tooley Street, S.E.

**Royal Surrey County Hospital, Guildford.**—Resident House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to the Hon. Secretary.

**Jersey General Dispensary and Infirmary.**—Resident Medical Officer. Salary £120 a year, with rooms, gas and attendance. Applications to Hon. Secretary, Infirmary, Jersey.

**Bracebridge Asylum, near Lincoln.**—Junior Assistant Medical Officer. Salary £125 per annum, with furnished apartments, &c. Applications to W. T. Sage Jun., Solicitor and Clerk to the Visiting Committee, 5 Back Street, Lincoln.

**Addenbrooke's Hospital, Cambridge.**—Secretary-Superintendent. Salary £250 per annum. Applications to the Secretary, 23 St. Andrew's Street, Cambridge.

**The Hospital for Sick Children, Great Ormond Street, London, W.C.**—Resident Medical Superintendent. Salary £115 per annum, with board and residence in the hospital and £5 washing allowance. Applications to James McKay, Acting Secretary, County Mayo Infirmary.—Assistant Surgeon, also to act as Compounder. Salary £140 per annum, with apartments, attendance, &c. Applications to Dr. M. O'Malley Knott, Resident Surgeon. (See advt.)

**Royal Hospital for Incurables, Dublin.**—Resident Medical Officer. Salary £120 per annum, with board &c. Applications to J. J. Thompson, Registrar. (See Advt.)

## Appointments.

**BREBLET, W. E., M.R.O.S., L.R.C.P.,** House Surgeon to the Women's and Children's Hospital, Leeds.

**LAURIE JAMES, M.B., C.M. Glasg.,** Medical Officer to the Smithstone Asylum and Poor House Greenock.

**LEE, E. H., M.D.,** Resident Physician Richmond, Whitworth and Bardwicks Hospitals, Dublin.

**RUTHERFORD, J. W., M.D.,** Resident Surgeon, Whitworth and Harwicke Hospitals, Dublin.

**ST. JOHN, WINSTAN T. A., M.B.C.S., L.R.C.P. Lond.,** Honorary Surgeon to the Derbyshire Hospital for Sick Children.

**TUMBER, H. STANLEY, M.B.C.S. Eng., L.R.C.P. Lond.,** Registrar to the Central London Ear and Throat Hospital.

## Births.

**WATSON.**—On Nov. 14th at 47 Mount Pleasant Road, Tunbridge Wells, the Wife of G. Trustram Watson, M.A., M.B., B.C., F.R.O.S., of a daughter.

## Marriages.

**BRYDEN-KETCHEN.**—On Nov. 17th, at All Saints' Eastmore Gardens, London, S.W., Charles Lumsdaine, son of the late Surgeon-Major J. L. Bryden, M.D. Bengal Medical Service, to Beryl Eme, younger daughter of Major-General L. Ketchen, late Royal Artillery, of 6 Nevern Mansions, London.

**LOMER-MESSUM.** On Nov. 16th at St. Stephens' Church, London, S.W., Capt. C. J. McIlreath Lomer, B.A. Hussars, second son of Cecil Wilson Lomer, Esq., late of Rosemore, Shirley, Haats, to Maude Antoinette, eldest daughter of Gordon Messum, M.D., of the Gables, Pretoria.

## Deaths.

**CHILD.**—On Nov. 18th, at Wei-hai-Wei, Cecil Edwin Criswick aged 29, surgeon R.N., H.M.S. Ocean, second son of the late Edwin Child, M.B.C.S. of New Malden.

**HORWOOD.**—On November 9th, at Coyton, Bournemouth, Sarah Elizabeth (Seia), the dearly loved wife of Dep. Surgeon-General Horwood (Ret.), A.M.D. aged 50.

**NEVILLE.**—On November 15th, at 70 Lower Mount Street, Dublin, Wm. Cox Neville, M.D., aged 49 years, second son of the late John Neville, C.E., County surveyor, co. Louth.

### COCAINISATION OF THE SPINAL CORD. (a)

By ROBERT JONES, F.R.C.S.,

Surgeon to the Royal Southern Hospital and the Liverpool Country Hospital for Children.

MR. PRESIDENT AND GENTLEMEN,—Spinal cocaineisation has been known among foreign surgeons as having distinct claims, yet very little is heard of it from our own people. It is because I believe that its employment is more often indicated than English surgeons seem to recognise that I venture to draw attention to two typical cases where its use proved of value.

A working man, æt. 30, was sent to me by Dr. Marsh, of Atherton. He had been a wilful, obstinate patient, who, in spite of every care on the part of his doctor, presented a malunited fracture of the lower third of the tibia and fibula. His foot was everted, and the lower fragments in addition were displaced backwards. I explained to him it was necessary to excise bone and wire fragments, and to this he at once consented. He was a big person, and as soon as he had taken two or three whiffs of chloroform he jumped off the table and scampered down the corridor and back to bed. Persuasive methods were unavailing, and Nature had so endowed him that we felt forcible methods had best be kept in abeyance. There was nothing left us but to dismiss him and to forget him. A fortnight later, his promises had been so alluring, we re-admitted him, and we underwent precisely the same experiences as before, and a second time he left the hospital. I explained to Dr. Marsh how impossible he was, but I promised to take him in a third time, and on this occasion determined to cocaineise his cerebro-spinal fluid. He submitted to this without protest. A fifth of a grain was injected between the third and fourth lumbar vertebræ, and in ten minutes all sensation left him to well above the umbilicus. He was an old poacher, and while I was operating he poured into the ears of Mr. Littler Jones anecdotes relating to his art. He exhibited no signs of pallor and nausea, and the only interest he took in the operation happened when I was chiselling through very hard callus—he then asked "what is that knocking?" He took a good meal when he went back to the ward, had no untoward symptom, and made an uneventful recovery.

The second case I present to you is that of a man of nearly sixty, who had always led an active

life, but had for some years been crippled by a disorganised tuberculous hip. I saw him with Dr. Warburton, and found his condition truly deplorable. He had fallen on his already diseased and painful joint. It was flexed to a right angle, tense, glazed, adducted, exquisitely sore. A foot-step on the floor, the closing of a door, a cough were followed by intense suffering. A splint he had always refused to wear. We removed him in a few days to a little ward in the hospital, where he arrived much exhausted and distressed. One then found that in addition to an abscess deep-seated, he had cavities in his lungs. The problem we put to ourselves was this—Are we justified in excising a hip, in an exhausted patient with a pulse of 130 and cavities in his lungs, so that should he survive the shock he might wear a splint with comfort and end his days comparatively free from pain? Our decision was made easy by the patient, who pleaded that death would be a grateful release from so much suffering. We decided to operate, and Mr. Alexander proceeded to administer chloroform. Only a few whiffs had been taken when the patient's face became blue, his pulse disappeared, and his extremities became cold. We thought he would die on the table, and he was hurriedly removed to the ward. The anæsthetic produced considerable shock, and for some days serious reaction occurred in the lungs. We decided on the next occasion to cocaineise the spine. His pulse was 140, and we sterilised very carefully the spine, using specially prepared hermetically sealed aseptic cocaine solution for injection. In from five to ten minutes his hip could be moved without pain, and he was carried into the theatre. A screen was placed in front of him, and the operation was proceeded with. Very rapidly a long incision was made, a large abscess of fœtid pus evacuated, the head of the femur removed, and the acetabulum scraped. When the femur was being sawn the patient said, "I know he is doing something to me now, for I feel my body shaking." Dr. Stenhouse Williams told me at the end of the operation that the pulse was steadier and better than when we started. The patient did not suffer appreciably from shock, his only discomfort being nausea, which lasted some hours. Several weeks have elapsed since the operation and the patient has lived a life he can bear with comfort, and he complains but little of his hip.

I have chosen these two cases as types in support of the undoubted value of this form of anæsthesia. In one case the patient would not take chloroform; in the other he could not. Cocaine in each instance answered admirably. Cases of this kind are common, and we all have met with many people who forego very necessary surgical procedures

(a) Read at the Liverpool Medical Institution, Thursday, November 17th, 1904.

because they refuse a general anæsthetic. A few words regarding the history and status of spinal cocainisation may not, therefore, be out of place.

It was first suggested and tried by Corning, of Chicago, but Bier and Ieldswitsch were pioneers on the Continent, and Tuffier of Paris, one of the most trustworthy and best of surgeons, used it as a routine anæsthetic. It is perhaps this use of it as a routine anæsthetic which has prevented English surgeons from doing justice to its usefulness. The concensus of opinions abroad is adverse to any attempt at substituting cocaine for ether and chloroform. About eleven deaths have occurred in about three thousand cases, all of which seem to be due to toxic poisoning. If for no other reason this should negative its routine employment. Some surgeons like Tuffier have been remarkably free from catastrophe. When I heard last he had operated upon over three hundred under cocaine, with only one death which might reasonably be ascribed to the drug. Morton, who, like Tuffier, is remarkably good in his *technique*, out of 253 cases had only seen alarming symptoms in one case, and in that case a quantity of cerebro-spinal fluid had been removed for investigation. Stone, out of 441 cases, met with only one death, and I merely mention these statistics in support of the argument that even if cocaine cannot compete with ether or chloroform as a routine anæsthetic, it is sufficiently safe to be used as an occasional substitute in suitable cases. Obviously, for its safe practise an irreproachable *technique* is demanded. The patient's skin should be scrupulously clean. The cocaine solution must be sterile. The glass syringe should be boiled and placed in sterile water. The needle should be introduced between the third and fourth or fourth and fifth lumbar vertebræ. It should be sufficiently long, fine, and not too acutely pointed. The patient should be made to stoop, and the needle should be introduced very slowly and in stages, in order to give the cerebro-spinal fluid time to escape. This is a most important point, otherwise it is easy to traverse the canal. No injection must under any condition take place until the fluid escapes through the needle. The causes of failure in reaching the canal are easily avoidable. They may arise from the needle impinging on the laminae, from failure of the eye to enter the canal, from a clot of blood or tissue, or from traversing the canal. If the needle does not reach the subarachnoid space, it should be withdrawn and re-applied. It is a mistake only partially to withdraw it. Thirty minims of a 2 per cent. solution should be a maximum dose. The cocaine should be introduced very slowly. Some surgeons advocate receiving the abstracted cerebro-spinal fluid in a sterile glass containing one grain of the drug, and re-introducing it into the subarachnoid space. The needle is withdrawn and the puncture sealed. When the injection has been completed, the patient soon feels a sense of warmth through his body, thirst which comes on in about five minutes, and a certain amount of nausea which lasts about ten or twenty minutes. If the patient attempt to walk, some inco-ordination is present, his sense of contact is not affected, but the reflexes are slightly diminished. Intestinal peristalsis and uterine contractions are stimulated. When first administered there is an increase of pulse and sometimes pallor,

perspiration, and vomiting, while sometimes the sphincter action of the vagina, rectum and bladder are abolished.

Analgesia usually begins in the feet and ascends slowly in from three to ten minutes, until it generally ends well above the xiphoid. There is often noted an abnormal loquacity. The analgesia usually lasts for over one hour, sometimes for two or three. The fatal cases have been generally due to direct toxic effects.

In order to convey a general idea of the frequency of annoying symptoms, I will quote Morton's analysis of 253 cases. The ages of the cases operated upon ranged from eight to eighty-six; many of the patients suffered from organic diseases of heart, kidneys and lungs.

Of 253 cases, nausea was present in	65
" " " vomiting	53
" " " headache	37
" " " invol. evacuation	9
" " " post-operative chill	6

One other not unusual symptom I will refer to, and this is a post-operative rise of temperature, ranging from 99° to 103°.

For tropa-cocaine, of which I have no experience, it is claimed that the effects are not nearly as toxic, and are recovered from more quickly, and that thirst, heat, vomiting, and perspiration seldom follow; against this some observers complain that its effects are not sufficiently constant to warrant its substitution for cocaine. Goinard, however, by employing cerebro-spinal fluid as a medium, has given seventy administrations of tropa-cocaine without an unpleasant symptom. It is very necessary, however, to place cotton wool in the ears, and place a screen before the patient to deaden him to his environment. Many symptoms may be due to fear; as Rodman says, discussing pallor, "no one can look at his own blood without misgiving and apprehension."

What are the contra-indications? On this point opinions differ very much. From the point of view of danger Tuffier warns us against giving it to the hysterical and to children. Others with less experience proscribe senile degenerations and renal affections. Morton, with his 250 cases, says there are no contra-indications, although he does not advocate its routine use. I suspect that until the dose is administered, nobody can tell the nervous system to which cocaine is a poison. In doubtful cases I would suggest that a very small subcutaneous dose might solve the problem as to immunity.

Tuffier, although he has performed 200 intra-abdominal operations, six of them being gastro-enterostomies, under cocainisation, thinks the operator may be somewhat handicapped by rigidity of muscle and occasional vomiting, and it seems generally conceded that the drug is best suited to those instances where operations are performed for herniæ, for bladder affections, and for serious operations on the limbs.

My feeling is that spinal cocainisation has come to us to stay, that with careful aseptic precautions the risks are but small; its indications point towards:—

1. Patients not suited for general anæsthetics, such as in those suffering from advanced phthisis and from respiratory affections like bronchitis and asthma.
2. Towards people who have a fixed aversion

to taking an anæsthetic, and on whom an operation is urgently needed.

3. Towards those suffering from great shock due to severe injuries of the lower limbs.

With caution in its employment, and the careful selection of cases, surgery has much to gain from cocaineisation.

## SOME ASPECTS OF METABOLISM—CHIEFLY CLINICAL. (a)

By WILLIAM CALWELL, M.A., M.D.,

President of the Ulster Medical Society; Physician to the Belfast Royal Victoria Hospital.

### PART II.

THE mysterious influences of the internal secretion of various organs now come into play. They add a new wonder to life, and are potent for good and evil.

This play of action and interaction form the symptom-complex of nutrition and malnutrition. There may be error in food or error in the preparation, or some defect, initial or acquired, in living matter, or perversion of internal secretion, or some mal-excretion.

The living protoplasm of the cells can apparently most easily assimilate the proteid in the serum, next the carbohydrate, and the fat with the greatest difficulty. The proteid molecule is the most complicated, but also most accommodating, too accommodating at times; not only does it give rise to the simpler molecules of ammonium carbonate and carbamate, but glycogen and a mono-saccharide can be split off, and fat finds a ready origin. This great huge lumbering mass of a molecule has, like the Empire of China, enough to give and to spare. Of all proteid molecules, the nucleo-albumens and cerebrals probably furnish the most complicated of all.

All the chemical processes of cells may be in time reduced to fermentation, the function of the living protoplasm being confined to the determination of the direction of the process at any moment. These ferments are innumerable; there are eight known unorganised ferments in the alimentary canal and a whole array in the body fluids. They bring about composition with an evolution of kinetic energy without themselves being used up in the process. If products of action are removed, the process can go on like the reversible action in chemistry. Those of you who practise the quantitative estimation of sugar by boiling an ammoniacal solution of citric hydrate are often puzzled how to decide when all the copper is exhausted. You boil and the blue colour disappears; but then, as you watch the solution on exposure to air, it regains some of its blueness. You repeat the process, and yet again repeat it. Apparently an indefinitely large quantity of the dextrose can be oxidised by the same solution of copper; this is one of the fallacies of this test; it is called the "reversible action," and in the inorganic world is analogous to the fermentation so richly found in physiological chemistry; the fallacy in practical work is of course avoided by noting the results at the instant that the blue colour first disappears. Another instance is the fact that spongy platinum will effect a rapid reunion between oxygen and hydrogen to form water. Ferment, then, is a factor which adds nothing to the total energy of the reaction, yet materially alters its velocity.

Of the vital action of the protoplasm itself we know little; it is the deepest physical secret of life, next to the material origin of consciousness; it is an ultimate fact.

This, then, is about as compressed a synopsis of the metabolism in our bodies as it is possible to make. From the evolutionary point of view, it is the result of millions of millions of experiments in plant and

animal life, during the last 50,000,000 years. Each living being has been a test tube wherein Nature has been experimenting; we but touch the fringe in the most advanced vital chemistry.

Can we propose now to examine into the question of disease arising—

1. From some perversion of the ferment action, by which albumen is converted into peptone and starch into dextrose;

2. From some perversion of the protoplasmic or synthetic action, by which peptone is re-converted into serum albumen and dextrose into glycogen;

3. From some perversion of the anabolic process of the most highly complicated molecules of living protoplasm throughout the whole body;

4. From some perversion of the katabolic or disintegrative processes?

This would be the theoretical course, but for practical purposes a different and more clinical course will be adopted.

1.—The natural variations in metabolism are infinite—age, sex, temperament, occupation, hereditary influence, and a hundred other minor causes all combine to form permutations and combinations of the force of which we can only make a sort of intuitive guess, but the exact value of which in an individual case under special circumstances baffles us completely when we endeavour to establish a careful estimate. You know of Professor Kraepelin's (of Heidelberg) experiments on certain fundamental properties of mind, as capacity for work, susceptibility to mental fatigue, the power of recovery from much fatigue, the power of concentration, the relation of bodily and mental fatigue, depth of sleep and so on. Many of these experiments and results might be applied by analogy to metabolism if we changed some of the terms. The forces of metabolism vary in individuals as much as the manifestations of nervous energy. They deserve to be more closely studied at the bedside. It is impossible to go into all the variations; two types will illustrate my meaning. We all know the big-boned child with a huge appetite, that is never fat; this type in adult life performs a vast amount of work at a spurt, but is rather deficient in staying power, and takes alcohol badly. The opposite type, the phlegmatic, rather cold child, with poor appetite, eats little, but still is fat; and in adult life often endures prolonged work, and even privation, and shows the strain but little; he can also take for years an unusual amount of alcohol, with at first, at any rate, apparently no further result than being a little too stout.

It is a pity that our old friends, choleric, melancholic, sanguine, and phlegmatic, have completely disappeared from our note taking; they point at the power and changeability of emotions and metabolism, which students now completely ignore, but which they subsequently learn from pure experience with no science to guide them. We should, however, remember the natural variations, and just as there is a slow burning coal and a quick burning coal, even to an explosive petroleum; and just as there is a coal with little ash, and a coal that soon puts itself out by its own accumulation, so we find endless variations in the firing of the human body.

It has occurred to me that we should have some clinical method of examining a patient's metabolism, as we examine his lungs, and heart, and brain. The methods that we find exemplified in experimental investigation in the *Journal of Physiology* are out of place by the bedside; in exceptional instances in hospital the chemical examination of food, urine, and faeces might be undertaken, but the possibility and advantage of any general practice would be more than dubious; as far as we can see, it would not be compensatory for the trouble. I am inclined to think that some such descriptions of the metabolism should be added to notes of our students in hospital.

II.—Next, of the changes that take place in acute starvation one does learn but little. I have seen one case of gastric ulcer where a return to feeding by the

(a) Opening Address delivered before the Ulster Medical Society, Session 1904-05.

mouth was delayed so long on account of previous hæmorrhage that the patient died from actual starvation supervening on excessive hæmorrhage at an earlier date. But although such an occurrence is rare, the gradual starvation that ensues in malignant disease of the cardiac end of the stomach, and the yet more complicated starvation that follows extensive and chronic gastric ulceration, is not uncommon. There was nothing in any of the cases that I have seen that struck me as very exceptional; the natural conservation of energy, the want of mental initiative, the small amount of urine and constipation form a familiar picture. No special examination of the excreta was made. But such cases form opportunities ready to hand for examination into metabolism.

As an instance of changed metabolism due to insufficiency of one kind of food and an excess of another, rickets suggests itself, and then scurvy; their study is valuable not only for the sake of the disease itself, but as types of disease that arise from some small deficiency in food, of little importance for one day, but when repeated daily, week in week out, giving rise to an affection which may be fatal in its severity.

III.—Excessive feeding has been well studied of late in our consumptive sanatoria, and an interesting problem faces us. In Vol. xxviii of the *Journal of Physiology*, details are given by Goodbody, Bardwell, and Clapman of an investigation into the metabolism of three ordinary healthy men, first on ordinary diet, secondly on excessive diet; the results are important, and are summed up as follows:—

The latter in all cases had to be stopped within a few weeks; loss of appetite, hæmorrhoids, dyspnoea on walking, mucous colitis; at first a rapid increase of weight, a subsequent rapid loss, and marked deterioration of health occurred in one or all. This result is interesting with regard to feeding of consumptives. Dr. Howard Sinclair and Dr. Burton Fanning have both written to me to the effect that the limit of diet is probably the same as in health; my own view is that it is more a question of deficiency before than excess after entrance to a sanatorium.

The question of an excess of carbohydrates in food is interesting. No excess of such simple articles of diet as rice appears to disagree in the ordinary individual. Excess of any forms of sugar, di-saccharides, or mono-saccharides soon disagrees, and the symptoms are too well known to need mention. If, however, we inject subcutaneously large quantities of dextrose, 5 to 7 grammes per kilo of body weight, so that it is acted on by the general tissues of the body, not by the liver, it is at once secreted by the kidney, and at the same time causes a marked increase of proteid metabolism. In fact, dextrose, or more probably an acid derivative of dextrose, under such circumstances acts like such toxic agents as phosphorus, poisoning the protoplasm.

These results (which I have taken from V. art. by James Scott, M.D., in *Journal of Physiology*, vol. xxiii) have a bearing on the boils and phthisis of diabetes, and also on the acne spots, the carious teeth of ordinary sweet eating; and this again leads to the variations in susceptibility to the evil effect of sweet-eating. To take our lesson from every-day life, one young lady can scarcely touch sugar without disfiguring her face; her companion in the parterre seems to think nothing of a box of chocolates, and retains the peach-like bloom unspotted. The "protective substance" in the latter must be well developed and able to overcome all the stray staphylococci lodging in her sebaceous glands; or the sieve-like action of her liver must be peculiarly delicate and efficient. People vary enormously in the power of dealing with not only alcohol, but carbohydrates and proteids, and we do not understand the secret.

IV.—Dr. Calwell then referred at some length to cases of diseases resulting from gastro-intestinal toxins and the consequent changes in metabolism. He continued:—

\* V.—Coming to the next class of cases—that by changes in metabolism due to affection of other organs

—I must be content merely to mention the diabetes mellitus that accompanies atrophy or removal of the pancreas; the causal relation is not known; the wasting without diabetes that follows cirrhosis of the pancreas, and has so often misled operators into the opinion of malignancy, is also recognised since Mayo Robson's publication.

Of the kidneys as influencing metabolism we meet not infrequently with the following type of case: A man over 60 complains of some loss of weight, but most of loss of strength and energy; there is a sub-normal temperature, large quantities of urine are passed with low specific gravity, this condition deepens, and after a lapse of a few months he finally dies, being conscious up to his death, perhaps a little delirious; his pupils are small, and there is muscular trembling and restlessness. Most probably an enlarged prostate, discovered during life, but on examination after death there is found hydronephrosis of both kidneys, with but little kidney substance left. This is Roberts' "latent uræmia," and its symptoms coincide very closely with Rose Bradford's results in removing portions of the healthy kidney. He found that when a fraction, say one-fourth, of the total kidney substance was removed, the urine increased in quantity, its specific gravity fell, but there was an increased excretion of urea greater than in health, and as high as when the animal was on a full diet, although now starving. When three-fourths of the total kidney substance was removed the wasting, the subnormal temperature, and great accumulation of urea were observed. There was no coma, convulsion, dyspnoea, vomiting, nor appreciable rise of arterial pressure. The symptoms are not those of Bright's, they point to a peculiar effect of the kidney—perhaps an internal secretion—on proteid metabolism generally. As the pancreas has some peculiar relation to carbohydrate metabolism, so the kidney has some relation with proteid metabolism.

With regard to the effects of the suprarenal bodies on metabolism, it must suffice simply to mention Addison's disease; similarly, with the pituitary body, acromegaly; with the thyroid, exophthalmic goitre, myxœdema, and cretinism; with the testes, the great change that ensues concomitantly with their growth during adolescence, their inhibitory influence on fat formation, their general stimulation of metabolism, and the quite as remarkable a change after their removal; the alteration in the female at puberty, at the menopause, and on artificial removal of the ovaries. The very strong effect of the cerebrum on metabolism is well known; an angry altercation, deep woe, any strong passion for a few hours, make one haggard, and bring down the weight by a few pounds. Literature is full of illustrations. Alienists tell us of the changes that come over the insane in this respect, wasting to excess in acute cases, overgrowth of fat in the dement, the necessity for terrific doses of purgatives all help the picture.

VI. and VII.—Time is left only to mention the effect of such toxins as the fevers on metabolism; and also the effect of such articles of diet or of luxury as alcohol, tea, tobacco, and of such drugs as phosphorus, arsenic, iron, mercury, and salicylate of soda, and last, but most interesting, of phloridzin. Pavy mentions 38 artificial conditions which have been reported as leading to the production of sugar in the blood, which is tantamount to saying glycosuria, as the amount of sugar in the urine is always an index of the sugar in the blood.

VIII.—In treating of the primary or idiopathic forms of diseases of metabolism, one enters upon the most difficult problems of pathology; as our knowledge becomes more exact and extensive, the group becomes smaller. For instance, many forms of glycosuria are secondary; secondary to the food, to functional disturbance of intestine and liver, to disease of the pancreas or of the brain. It is curious that diabetes or glycosuria is not associated with any organic disease of the liver. There still remains however, an apparently primary diabetes mellitus, where sugar appears in the urine, although carbohydrates are disallowed and liver, pancreas and brain show no evidence of disease.

where apparently a dextrose escapes into the blood stream from the huge molecule of living protoplasm, from its own intrinsic weakness of combination. This is the "composite" diabetes of Pavy; whether the excess of urea that accompanies the sugar is also due to the primary disintegration of proteid, or is secondary to the sugar, as in the case of the subcutaneous injection of dextrose, is unknown. The questions of pentosuria, of levulosuria, of glycolytic action of the blood, are yet too *sub judice* to allow any practical deductions to be made.

The opposite type of a primary disease of metabolism is obesity; the tendency is often hereditary; it seems to be a faulty tissue, not a simple failure to effect oxidation. Whether at all, or how far, it is connected with the thyroid gland is uncertain, but cases have been reported of the gland having been found changed. As an instance of the want of proper testing of methods of treatment, Von Noorden relates the case of a stout lady, who submitted to massage of one arm; massage was a vaunted remedy for obesity, and warranted to remove an overplus of adipose tissue; however, at the end of a suitable time, the circumferences were again measured: the arm which had not undergone treatment remained as before; the other had increased one and a half centimetre.

I now come to some other, rather rarer forms of apparently primary disorders of metabolism. One has received the name azoturia; it is a rare condition, we commonly enough see milder forms of it, or perhaps more truly, we see mild acute attacks of it; there is an excess of urea and urates; this causes a certain amount of polyuria, a feeling of languor, weariness in loins and thighs, a disordered stomach, dirty tongue, and disturbed appetite, with loss of weight. I have seen several mild instances of it, and the patients were all more or less under the influence of some pretty powerful emotion. As a pure proteid diet does not stop a primary diabetes, so a pure carbohydrate does not stop this azoturia. Some cases are reported as running into diabetes. An analogous condition called baruria, where there is a general pathological increase of the solid constituents of the urine, is also reported; the symptoms are much the same as in azoturia. Whether under this head we should include diabetes insipidus or not is debatable. However, we must include "phosphaturia" or "phosphatic diabetes," of which most of us have come across at any rate mild types of, although a rare affection. By this term is not meant phosphates deposited in alkaline urine, or the triple phosphates due to decomposition, but a pathological constant increase of earthy phosphates. We find phosphates somewhat excessive in gout, where it may alternate with uric acid, and also in the opposite kind of disease, namely, phthisis; phosphates are said to be increased by administration of ovarian substance; and although excess of these salts is not found in mollities osseum, yet removal of the ovaries is said to arrest this disease. Like uric acid, phosphates are derived chiefly from the food, but some come from tissue disintegration; the urine removes the alkaline phosphates, but the mucous membrane of the intestine removes the phosphates of calcium; and, lastly, phosphates are diminished in Bright's disease and are in excess where uric acid is in excess—namely, where there is a breaking up of nuclein into its proteid and purin radicle. It is said there may be a renal inadequacy for phosphates, as there is for urea, and as we shall see for chlorides. Von Noorden lays considerable stress upon these phosphates, and advises in Bright's disease the administration of carbonate of calcium several times daily in milk, as he says by this means half of the phosphoric acid remains in the intestine, or after circulating in the body is poured into the intestinal secretion and appears in the fæces, and so the kidneys are spared. We thus see that there is more than empirical reason for adding lime water to milk.

The symptoms of phosphaturia are much the same as in azoturia—namely, emaciation, nervous irritability, dyspepsia with pain in back and loins; and the ill-health may deepen into phthisis or diabetes.

Under the same heading and with much the same symptoms comes oxaluria, which need not delay us.

While on this subject of what has been called the "demineralisation" of the tissues, one must not omit the theory lately advanced by some French clinicians, that if sodium chloride is not eliminated by the kidneys at a rate proportional to its absorption, the salt accumulates in the tissues, causing a hydration which leads to œdema. The excretory power of the kidneys for common salt in some cases of Bright's disease is less than in health; the opinion was advanced that chloride retention was a sign of renal inadequacy. The figures given are as follows. A man eats about 15 grammes of salt every day; healthy kidneys can excrete more than 30 grammes, but diseased kidneys perhaps not more than 2 or 3 grammes; urea, phosphates, and other urinary constituents may remain normal. In some cases of tubular nephritis with œdema there is a renal inadequacy for sodium chloride; the opposite condition is said to exist in some cases of chronic interstitial nephritis, in which a state of hyperchloriduria is present, by which the tissues are dechlorinated. We thus seem to have a disassimilation for nitrogen, for phosphates, and now for chlorides. On the other hand, in one case, more chloride was excreted than had been absorbed; the tissue, instead of fixing some of the salt, had lost part of what it had already held; the symptoms were polyuria, thirst, absence of œdema, and hyperchloruria. On *post-mortem* examination both kidneys were very small. (*Practitioner*, November, 1904.)

The result of these statements is that in future we must pay more attention to the quantitative analysis of urine for such salt, and endeavour to find out in how far they are primary diseases or merely signs of a disease. The treatment of all these conditions of which pathology is obscure, but in which the nervous element in my experience is the most important, is much the same—rest, quietness, removal from all sources of emotion, cold salt bathing or sponging, and acids, cool rooms, and light clothing and purified food. Of drugs, I think opium should be tried in cases that do not yield to hygienic measures.

## A FATAL CASE OF ŒDEMA ASSOCIATED WITH ALBUMINURIA IN AN INFANT AGED EIGHT MONTHS. (a)

By GEORGE CARPENTER, M.D.,

Senior Assistant Physician to the North Eastern Hospital for Children; late Physician to the Evelina Hospital for Sick Children.

MAUD S., æt. 8 months, was brought to the North Eastern Hospital for Children on December 7th, 1903, with a history of having wasted since measles, ten weeks previous. Her abdomen was prominent, and her liver extended three fingers' breadth below the costal margin in the nipple line. She was neither rickety nor anæmic, and there were no physical signs. Her mother had borne six children; she had one born dead and one still-birth, and had produced three children, living, since then. On Dec. 4th the child was considered to be progressing well, but a week later her face began to swell, and then her hands and feet. The illness commenced with sickness every time she took the breast. She did not pass much water, and it was said to be a "kind of brown colour." On January 4th her face was waxy-looking; both eyes were œdematous, the right eye especially. The feet and legs were very dropsical, deeply pitting on pressure, also the trunk; and the feet were cold and blue-looking. The buttocks and groins were raw-looking and weeping. On the right cheek there was a tiny cutaneous gamma

(a) Read before the Society for the Study of Disease in Children, February 19th, 1904.

with a reddened surface, the size of buck-shot. The mucous membranes were rather pale. There was also a number of superficial lesions on the cheeks, the size of hemp-seed, with a certain amount of surface exudation, which the mother said came out like yellow blisters. She was admitted into the hospital. On January 7th the œdema of the trunk had increased slightly, and that of the eyes had decreased. The spots on the face were more numerous. The smallest quantity of urine which had been passed was 4 ounces in the twenty-four hours, the largest 5 ounces. The highest pulse-rate per minute was 116, the lowest 92; the highest respiration-rate 36, the lowest 24. The temperature was about 97° F., the highest 97.8° F. There was a decided cloud of albumin in the urine, and a sediment on boiling. On January 8th the œdema was less on the dorsa of the hands, and on the right side of the trunk. œdema was well marked on the inner side of each thigh, the fronts of the legs, and the backs of the feet. There was slight œdema round the umbilicus. The most marked swelling was on the buttocks, where several drops of serum could be seen exuding from the surface, which was red and shiny. There was no lumbar œdema. On January 9th the urine was thick and cloudy, and contained 1 gramme of dried albumin per 1,000 c.c. The urea amounted to .4375 grain per ounce. The œdema was less in the morning than at night. On January 10th there was a slight trace of albumin, and the urea was .4375 grain per ounce. On January 11th there was a slight trace of albumin. The swelling was slightly less than before. On January 12th there was a slight trace of albumin; there were no tube casts. The largest quantity of urine that had been passed since the previous record was 5½ ounces, the smallest quantity 3 ounces. The child was in a very precarious condition; no radial pulse could be felt, and the breathing was shallow and irregular, and she died on January 13th. The *post-mortem* examination was made on the same day. The brain, which weighed 23 ounces, was normal. The heart was healthy. The right lung weighed 2½ ounces; it was in part œdematous. The left weighed 2½ ounces, and was in a similar condition. The liver was pale; it weighed 11½ ounces. The right kidney weighed 1 ounce, the left 1½; neither appeared abnormal. The spleen weighed ¾ ounce. The stomach and intestines were normal. Microscopically, nothing abnormal was detected in the kidneys. The liver was fatty; the heart was normal. Some small patches of broncho-pneumonia were found in the lungs.

*Remarks.*—In the absence of definite pathological changes in the organs one is forced to fall back upon the explanation of toxæmia to account for the symptoms during life, though how and where the toxin was manufactured which produced the fatal result the autopsy does not show.

## Transactions of Societies.

CLINICAL SOCIETY OF LONDON.  
MEETING HELD NOVEMBER 25TH, 1904.

DR. FREDERICK TAYLOR in the Chair.

### CRISES IN COURSE OF POSTERIOR BASIC MENINGITIS.

DR. C. R. BOX read a paper on certain paroxysmal exacerbations of symptoms which occur during the

progress of posterior basic lepto-meningitis in patients whose cranial fontanelles have closed. These exacerbations he proposed to call "the crises of posterior basic meningitis." In the most complete form this complex of symptoms is as follows: The temperature suddenly rises from subnormal or near normal to a considerable height—it may be as much as 7° F. The patient experiences a feeling of chilliness or even has a rigor. Headache, frontal or vertical, sets in and often is accompanied by vomiting. The neck becomes stiff or retracted and the mental condition is dull. At the same time the pulse-rate does not fall, but, on the contrary, is usually increased. The temperature remains high for a short time and then may fall as abruptly as it rose, the urgent symptoms at the same time subsiding. The whole crisis may be over in a few hours, or it may be twelve hours or even more before the normal condition is regained. In one case the lateral column symptoms, exaggerated knee-jerk clonus, &c., were decidedly exaggerated during the paroxysms. Five cases were reported, three of which showed the crises in a typical form and two in which the crises, although present, were not so prominent. Lantern slides of the temperature charts were demonstrated. Dr. Box remarked that this form of paroxysmal pyrexia was not included in the list formulated by Murchison, but apparently was recognised by Bristowe. Attention was drawn to the fact that the co-existence of secondary deafness or of secondary otitis media in posterior basic meningitis might give rise to considerable difficulty in distinguishing cases in which the crises occurred from cases of ear disease with secondary intracranial complications. Temporary increase in the intra-ventricular pressure was suggested as the cause of the exacerbations, and the advisability of lumbar puncture or of some other operation for the relief of the pressure was suggested.

DR. F. E. BATTEN was not familiar with the class of case described, as they were in patients over the age of nine. In young children, however, he had frequently observed this sequence of symptoms. He asked what evidence there was that the cases were true posterior basic meningitis, *i.e.*, due to Weichselbaum's diplococcus. He hardly thought the term "crisis" an appropriate one, as that indicated either a turning-point or a critical period. The rise and fall in temperature might occur as described, with no other symptom except a little cyanosis of the extremities. The fall was just as characteristic as the rise, and he had seen greater falls, *e.g.*, to the extent of 10° F. in twelve hours. As, however, the same series of symptoms might occur in such conditions as hydrocephalus, middle ear disease, suppurative pericarditis, he could not agree that they were characteristic in any way of posterior basic meningitis.

DR. PASTEUR thought that the term "crisis" was a bad one. A point that struck him was that the drowsiness was present in between the attacks, and not at them, this being much against their being due to increased intra-ventricular pressure.

DR. TAYLOR similarly wanted to see justification for the use of the term crisis, though it had a wider meaning than that given by Dr. Batten, as evidenced by its use in locomotor ataxy. He had never seen the phenomena described in the course of posterior basic meningitis, but had seen it on one occasion apart from that condition.

DR. BOX said that he applied the term to the whole syndrome and not to the temperature alone, and thought that he was justified by its use in reference to floating kidney. Bacteriological tests were applied in only two cases; in one a streptococcus was obtained and in another an organism of indeterminate nature. Clinically, however, the cases were clearly posterior basic meningitis.

A CASE OF UNILATERAL TUBERCULOUS MENINGITIS IN WHICH A BULLOUS ERUPTION FOLLOWED LUMBAR PUNCTURE.

DRS. H. D. ROLLESTON and TEBBS described the case

of a boy, *æt.* 5, who was perfectly well until, after a day's malaise, he was seized with general convulsions, more marked on the right side, with conjugate deviation of the head and eyes to the right. Lumbar puncture was performed between the spines of the third and fourth lumbar vertebræ, and subsequently a cannula was introduced in this position and cerebro-spinal fluid, which at first was blood-stained, allowed to run away. On the following day, on the afternoon of which death occurred, two bullæ appeared on the outer aspect of the right little toe. The whole illness occupied five days. At the necropsy there was tuberculous meningitis, limited to the left Sylvian fissure, which was thought to be due to an embolus derived from a caseous gland invading the apex of the left lung. There was an elongated blood clot three inches long under the arachnoid and in contact with the posterior nerve roots of the cauda equina on the right side. This clot, which was probably due to lumbar puncture, was regarded as having irritated the posterior nerve roots and ganglia and produced a bullous eruption resembling herpes.

Dr. Box said that the case was of interest in that it showed that lumbar puncture, though of great service, was not always harmless. He had twice seen extensive intra-meningeal hæmorrhages follow the operation.

Dr. BATTEN asked whether the first sacral ganglion had been examined. He pointed out that the posterior root ganglion was some distance away from the site of puncture. The evidence that a subdural hæmorrhage, or any other injury of the posterior nerve roots apart from the ganglion, could produce a herpetic eruption was very slight.

Dr. A. E. RUSSELL said that the case was of considerable interest from a physiological side. Bayliss had shown that stimulation of the peripheral end of a cut posterior nerve root caused great vaso-motor changes in the limb supplied.

Dr. H. D. ROLLESTON said that the sacral ganglion had not been examined.

#### POST-OPERATIVE ACUTE LOCAL TUBERCULOSIS.

Mr. EDRED M. CORNER and Dr. LEONARD S. DUDGEON described a case in which, after an operation for tuberculous glands of neck, a local tuberculous infection of all the surrounding tissues occurred. The chief sign of this infection was local swelling after the wound had healed. The case therefore sheds light on the nature of "swellings" seen after operations for tuberculous lesions. Several cases were narrated to illustrate this in connection with glands of neck, tuberculous disease of the knee-joint and kidney. In these instances, and in many more, not specifically quoted, the healing of the wound had been by first intention. Local infection does not seem to occur, or perhaps it occurs only in lesser intensity and degree if the wound is left open or drained. The question of the advisability of the employment of drainage after such operations is raised; and where there has been obvious chance of infection occurring, as if glands burst whilst being excised, and the situation allows of it, the sounder surgery is to close the wound incompletely and employ drainage.

Mr. F. C. WALLIS urged that better results than those described were obtained by draining the wound for twenty-four hours so as to allow of the escape of the inevitable collection of serum that took place.

Mr. W. G. SPENCER had never seen such a case after antiseptic operations. He thought that its occurrence was due to incomplete removal of diseased tissue, and urged more extensive operations in tuberculous cases. He had been impressed by the latency of tubercle bacilli. This was well shown in the lighting up of old foci after injection of Koch's tuberculin. The activity of the micro-organisms was far larger than appeared clinically.

Mr. R. P. ROWLANDS asked whether in the kidney case described infection through the ligature could be excluded. Another fallacy was disease of the ureter. He had seen recurrence after this had been incompletely removed.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND.

##### SECTION OF OBSTETRICS.

MEETING HELD NOVEMBER 18TH, 1904.

DR. A. J. SMITH, President, in the Chair.

DR. A. J. HORNE showed a case of Elephantiasis of Leg and Vulva.

Dr. W. J. SMYLY showed a specimen of Cancer of Both Ovaries. Patient, *æt.* 66, ceased to menstruate at 54. In April last there was a slight red discharge which ceased, but came on again in three months. Scrapings from curetting were benign. A small tumour could be felt on each side of uterus. In November a large ovarian cystoma had formed. Uterus and both ovaries were removed by Doyen's method. The second case was Tuberculous Pyosalpinx, and in it the uterus and appendages were removed by the same method.

Dr. E. H. TWEEDY asked if there were adhesions behind the uterus in these cases, as Doyen only employed his operation for myoma of the uterus. Also, would he remove pyosalpinx by that method in every case?

Dr. R. D. PUREFOY thought the question of diagnosis was interesting. A malignant tumour sometimes simulated pedunculated fibroid very closely. He did not see why the uterus should be removed in every case of removing the tubes. He had found great advantage in operating on these cases from trying the ovarian artery in the infundibular pelvic ligament.

Dr. KIDD thought it too sweeping to say that the uterus should be removed in every case of removal of the tubes. He related a case of pyosalpinx of both tubes, which drained into the uterus from time to time. The patient was too weak to be operated on. She afterwards got perfectly well, and bore a living child.

Dr. A. J. SMITH said he used to be content with removing the tubes in tuberculous disease, but then found that patients often came back complaining of pains, which he thought were due to adhesions. In one case he operated again and found a large tuberculous mass, and now he always removed the entire uterus. In ordinary cases of pyosalpinx he had not yet adopted it.

Dr. PUREFOY wished to know how one would recognise these cases of tuberculous tubes, if he advocated the removal of the entire uterus in these cases only.

Dr. SMYLY, in replying, said that in these cases of pyosalpinx, tuberculous or gonorrhæal, the tubes were twisted and surrounded by dense adhesions, rendering it very difficult to get them out. The chances were very much against cases being like Dr. Kidd's, in which there was drainage. His own experience was like Dr. Smith's—that is, having patients coming back after removal of the tubes only, and he thought now that the uterus should be removed in most cases. In the case he had shown there were a lot of adhesions behind the uterus.

#### DR. A. J. HORNE opened a discussion on THE INFLUENCE OF FIBRO-MYOMATA ON PREGNANCY AND PARTURITION.

Dr. W. J. SMYLY said that the general impression was, that women with fibroids were less likely to conceive than others, but these women were generally sterile long before. The cause of sterility appeared to be the condition of the mucous membrane. Another point was that these women went on bearing children to a later period in life than others, and it was attributed to ovulation and menstruation going on to a later period. His own experience did not either support or contradict these opinions. He thought that these tumours did not often cause obstruction during labour, even when growing low down in the pelvis, as they were usually drawn up out of the way. He related a case in which there was a subperitoneal myoma, pushing the peritoneum up, and the vaginal mucous membrane down. He had to do Cæsarean section and remove the uterus and tumour. In another case there was an interstitial myoma in the lower uterine segment. The patient went into labour for a few hours, and then labour pains apparently ceased; came on again in a few hours, and membranes ruptured.

She was in labour on and off for a week. The os then allowed two fingers in, and a foot was pulled down, and after a long time the foetus came away. He thought the chief danger of myomata was during the puerperium. In one case a hospital patient died from *post-partum* hæmorrhage, and, *post-mortem*, a submucous myoma was found, the size of an orange. He had also found that portions of the membranes were retained sometimes in these cases, which decomposed and caused sepsis. Retained placenta was also common. He did not agree with Bland-Sutton that all myomata should be removed, though the risk of operation was not great.

Dr. PUREFOY thought the influence of fibroids in causing sterility was over-rated. An interesting aspect of the question was the greatly increased difficulty in diagnosing pregnancy in the first three months. If a myoma invaded the cervical region it was most difficult, as he thought the cervix did not undergo the characteristic amount of softening of pregnancy. He related a case in which a fibroid occupied the pelvis, and he did Cæsarean section. A fibroid in the uterine wall also enfeebled the uterine contractions, and they often caused marked interference with the course of labour. He related another case of a primipara, æt. 30, with a fibroid in the lower uterine segment. She went five weeks beyond full term. The presenting part could not be reached, and there was a complete absence of labour. The uterus was removed along with the child, and the patient made a good recovery. Displacement should be done in these cases if possible, and he thought myomectomy was only advisable in the early months of pregnancy. He tabulated these cases in the Rotunda, and noticed an absence of *post-partum* hæmorrhage. Most of the patients were young women, æt. between 30 and 40. He suggested that the occurrence of pregnancy rather hastened the development, and increased the size of these tumours.

Dr. E. H. TWEEDY related a case in which he had removed the uterus at the fifth month, as the patient could not have gone on to full term. As to fibroids causing sterility, he said it was not the fibroids, but the endometritis that caused it in a certain number of cases. If there was a subperitoneal myoma it would not cause endometritis, and there would be no sterility. Another point was that they might directly cause twisting, or pressing, or stretching of the tubes, which might cause sterility.

Dr. KIDD agreed as to the difficulty of diagnosing pregnancy in the early months, when associated with myomata. As to sterility, he thought the question was one of comparative and not absolute sterility. He related a case of a primipara, æt. 44, with two large tumours at the fundus. They caused transverse presentation; version was done. The placenta had to be removed manually. Patient made a good recovery. He had examined the patient since, and found that the tumours had entirely disappeared. When pregnancy was complicated by cancer, the cancer usually increased rapidly, owing to the hyperæmia. He thought the same increase usually occurred in the case of other tumours under similar circumstances. He related another case in which a tumour sprang from the posterior wall of the supravaginal portion of cervix. Panhysterectomy was performed, and the patient made a good recovery. In another case in which a tumour was present which could not be lifted out of the pelvis, Cæsarean section was performed. Two years later the patient again came into hospital, after she had been in labour for 73 hours. On this occasion it was possible to deliver her with forceps. In another case labour was induced, but soon ceased. A tumour, the size of a hen's egg, was then enucleated from the cervix; after ten days labour came on again, and the patient delivered herself.

Dr. JELLETT said that another aspect of the question was the effect of myomata on the life of the ovum during the last months of pregnancy. Quite recently, he had had a case in which death of the foetus *in utero* apparently resulted from a myoma of the fundus. He saw a patient in February last who was expecting

to be delivered about May 1st. She went all through May, and then a myoma, the size of a cocoanut, was found on the anterior wall of the fundus. A dead and macerated child was born on June 3rd, and the placenta was little more than the normal size. He was interested to know if such a case could be attributed to the myoma, or whether it was a mere accident of pregnancy. If the former, there were two views of the case. First, was the patient's history correct, and should she have been delivered on May 1st, and did the myoma affect the innervation of the uterus, and prevent labour coming on at the proper time? Secondly, did the myoma interfere with the development of the placenta? This was probably the correct view. Four months after the labour he found another myoma on the posterior of the fundus, so that there was very little healthy area at the fundus for the placenta. It then became a question of how close the myomata lay to the mucous membrane, as if they lay very close there might not be sufficient room for the uterine sinuses to develop and hence an insufficient circulation. After a certain period, then the foetus would die from interference with the placenta. One cause of sterility in cases of uterine myoma was probably to be found in cystic degeneration of the ovaries.

Dr. A. J. SMITH related two cases. The first had a large fibroid tumour, the size of an eighth months pregnant uterus. There were no urgent symptoms, but there was no room for a pregnant uterus along with the tumour. He removed the tumour and the following year the patient was delivered of a full term child, and had had four since. The second case was one of six months' pregnancy, complicated by a large fibroid tumour. There was great distress and dyspnoea, and the tumour was removed along with the pregnant uterus. This was another example of the danger of a large fibroid tumour in pregnancy.

Dr. A. J. HORNE, in replying, said he never knew of a primipara, æt. more than 47. He said there were two questions he had avoided in his paper, first, the diagnosis of fibroids with pregnancy, and, second, their after-effects on the puerperal state. In the case he had with Dr. McArdle, the patient was six months pregnant. There was a tumour in the right hypochondrium, which overshadowed the uterus, but there was a distinct line of demarcation. It only gave rise to slight pressure symptoms, and the pregnancy went on to full time. There was a breech presentation. As to *post-partum* hæmorrhage, he had always referred to the danger of it in these cases, but had seen many without it. He did not see how sterility was caused by pressure on the oviducts, as in these cases there was excessive menstruation.

THE BRITISH LARYNGOLOGICAL, RHINOLOGICAL AND OTOLOGICAL ASSOCIATION.  
ANNUAL GENERAL MEETING HELD NOVEMBER 11TH.

MR. BARK, and subsequently MR. CHICHELE NOURSE presiding.

A VOTE of thanks to the retiring president, Mr. Bark was proposed in terms of cordial appreciation by Dr. DENNIS VINRACE, who referred particularly to the long distance travelled by Mr. Bark in order to carry out his presidential duties. This was seconded by Dr. WYATT WINGRAVE, and carried unanimously.

Dr. KELSON described a case in which the patient came complaining of hoarseness of several years' duration, but recently increasing. There was no history of syphilis, tubercle, or malignant disease. On examination, a pinkish growth was to be seen occupying the anterior commissure and anterior part of the left cord. A portion of this has been removed, and proved to be a papilloma. The movement of both cords was good.

Dr. WYATT WINGRAVE showed a case of "Salivary Calculus Simulating Angina Ludovici in a Male, æt. 30." A male patient came to hospital with considerable swelling immediately beneath the jaw between the tongue and the hyoid bone. It was very painful.

and he could not open his mouth more than half an inch and there was considerable difficulty, not only in breathing but in swallowing and masticating. The voice was characteristic of that of a patient suffering from acutely inflamed tonsils. The swelling all round led him to the belief that it was a case of angina Ludovici, perhaps associated with inflammation and suppuration of the lingual tonsils. As far as he could see the latter were distinctly enlarged and they completely hid the epiglottis. But on running the fingers along the floor of the mouth and around the tongue he came upon a hard resisting surface at the side of the frænum, and that he pressed upon, perhaps more than usual, and discovered a very hard point projecting. It was a salivary calculus, and when the calculus was removed there was a discharge of pus from the surface. The swelling went down and the patient was all right in a few days. The case was interesting from the point of view of differential diagnosis. The stone was in Wharton's duct.

Mr. W. STUART-LOW explained that Dr. Abercrombie had hoped to be present, but found it impossible, and he had therefore asked him to read the following description of a somewhat similar case:—In connection with Dr. Wingrave's case, the following notes of a similar one occurring in my (Dr. P. H. Abercrombie's) practice may prove interesting. I was consulted on April 25th last by a man, æt. 54, a commercial traveller, who complained of a painful swelling under the chin and left side of the tongue of between two and three weeks' duration. The swelling, which was very evident on inspection, was situated under the chin and the left side of the lower jaw, and was hard to the touch and very tender. It had pushed up the tongue and interfered with speech, and swallowing was difficult and painful. There was considerable constitutional disturbance, and the patient's facial aspect was one of great suffering and anxiety. Carious teeth were present in the left lower jaw, and there was enlargement of the left submaxillary lymphatic glands. I incised the sublingual swelling in the mouth and some fetid pus escaped, but I failed to detect any stone with the probe. A few days later, however, the two specimens of salivary calculus which I show to-day were found loose in the mouth, and removed by the patient. After this he recovered rapidly, and was soon quite well.

Dr. WYATT WINGRAVE on a case of "Epithelioma of the Laryngo-Pharynx, wearing Jacques' Œsophageal Tube." The patient was a man, æt. about 60, who came eight or nine months ago to the hospital complaining of difficulty in swallowing. It was evidently a case of epithelioma involving the lower part of the laryngo-pharynx. The infiltration was extensive, so that it was inoperable, and in order to feed him a Jacques' tube was passed through the Œsophagus into the stomach, and then it was caught by passing a loop through the nose, and brought up through the nostril and carried over to the ear, where it was fixed. The man was then taught to introduce the food by that means. It was interesting from the point of view of how long such a state of matters could exist. The man had never had the tube out for seven months, and beyond a certain amount of discomfort from the factor he was none the worse for it. It certainly was not very nice, from an æsthetic point of view, to have a tube over the ear, but the patient could swallow with it, and feed himself remarkably well. He was now able to correct the unpleasant factor which existed at first by having a mouthful of sanitas and water and swallowing it until it reached the constriction, and then eructating. The pain was so great that he ordered him a grain of powdered opium to mix with his tobacco, and that gave him more comfort than anything else. The last he heard of the patient was that he was doing well, and that he had not lost in weight.

Dr. KELSON agreed with Dr. Wingrave with regard to the utility of those tubes in such cases, and described a particular case.

Mr. BARK thanked Dr. Wingrave for bringing the case forward. One knew the difficulty there was in conducting comfortably and peaceably those inoperable

cases to their final destination. His own experience in the use of tubes for feeding and the dysphagia produced by laryngo-pharyngeal carcinoma had been in the use of Symonds' tubes. He had found those tubes very unsatisfactory in most cases. The patient very soon rejected the tube. He was very pleased to hear of the Jacques' tubes and that they could be retained in order to feed the patient, who would otherwise inevitably die of starvation.

Dr. ANDREW WYLIE: Case of "Epithelioma of the Auricle."

Mr. STUART-LOW apologised for the absence of Dr. Wylie, and said that gentleman desired him to ask the opinion of Fellows as to whether he should operate in that case, which had been proved microscopically to be epithelioma. Could the whole of it be got away by operation?

Dr. HASLAM (Croydon) asked whether there was any enlargement of the lymphatic glands in the case.

Mr. STUART-LOW replied that the deep lymphatics were enlarged, and also those well behind the jaw. Of course, the operation would have to be a very radical one, and that was why Dr. Wylie was doubtful as to the expediency of operation.

Dr. WYATT WINGRAVE thought an entire removal of the disease was fairly probable, although it was difficult to say to what extent the meatus was implicated, and how far the growth was connected with bony wall.

Dr. DUNDAS GRANT: "Exostosis of the Auditory Meatus."

Dr. ATKINSON, in Dr. Grant's absence, explained what had been done in the case. The exostosis presented close to the external auditory meatus, and he first of all used a dental burr, and into the aperture made by it introduced an instrument like a large wool-holder, working in a corkscrew fashion. He simply twisted that in, and the exostosis came out quite easily. There seemed to be none of the growth left behind.

Dr. HASLAM (Croydon) asked why Dr. Dundas Grant operated in the case, because he believed it was an understood thing that the best plan was to leave an exostosis alone unless it was complicated by disease. Was it a pure exostosis, the result of which was some obstruction and deafness?

Mr. BARK said that evidently an exostosis of that size in the external auditory meatus would cause a large amount of deafness, and if it were easily removable, as in the present case, that operation would be perfectly justifiable. The exostosis appeared to have had a pedicle, and therefore it was an excellent case for removal.

Dr. WYATT WINGRAVE showed a case of "Primary Chancere of the Nose."

Dr. VINRACE said he did not feel satisfied as to it being a primary ulcer of the nose. He asked whether the inoculation was not due to conception. One often saw such cases where the subjects were healthy until pregnancy, and then they showed manifestations in different parts of the body. Possibly the nose was an uncommon site, but he thought it would be found to be secondary to needle inoculation.

Dr. WINGRAVE said that, first of all, the patient had a slight discharge from her nose. There was swelling and stiffness referred to the root of the nose. That disappeared, and in a short time a small pimple showed itself at the edge of the nostril, which gradually spread but did not discharge. The discharge came from the interior of the nose. The swelling got much harder, but about three weeks ago it began to soften. She had complained for the last week or so of an amount of soreness in the throat. But in addition there was a well-defined rash, which had been partly on her trunk, but chiefly on the extensor aspects of the forearms, and to some extent on her legs.

Dr. VINRACE said he feared he had been misunderstood. He did not doubt the nature of the complaint—it was syphilitic, but he doubted the actual causation of the lesion. He regarded it as a case of inoculation through the fœtus and not an inoculation by direct

contact, forming a primary sore. Was the patient pregnant or not?

Dr. WINGRAVE, in further reply, said he could not give any history with regard to the inoculation. She had been married fourteen months, and the woman did not think she was pregnant.

Dr. WYATT WINGRAVE showed a case of "Cystic Disease of the Antrum."

The PRESIDENT showed a case of "Disease of Sinuses." He said it was a case of disease of sinuses in which a permanent opening had been made into the inferior meatus of the nose.

Mr. BARK said he was never in favour of treating antral suppuration by an opening such as that described. He preferred, if he were going to make an extensive opening into the outer wall of the nose or the inner wall of the antrum, to do the complete operation, to remove the external wall and the superior maxilla. If for any reason, such as the objection of the patient, he could only do a tentative operation, he preferred to make an opening into the canine fossa and insert an indiarubber tube, by means of which the patient could cleanse out the antrum through the nose.

The PRESIDENT replied that he had a particular reason for not doing the radical operation in the present case. One point was that it was not clear to his mind whether it was a case of simple myoma or actual sinusitis of the antrum. And in cases where one desired to open the sinus without doing the radical operation he certainly did not care to make an opening into the mouth, because the mouth, being a septic cavity, it very often happened that re-inoculation took place and the suppurative abscess continued indefinitely. That patient had had no trouble whatever in the manipulation of her tube; she passed it quite easily, and it kept the sinus washed out. Otherwise he endorsed Mr. Bark's remarks about the desirability of doing the complete operation.

The PRESIDENT showed a case of "Maxillary Sinusitis." It was shown on account of the ease with which the sinus could be catheterised through the infundibulum.

Dr. VINRACE asked how long it was suggested catheterisation should take place. Was it to be done to the end of the patient's life, or gradually relaxed and finally left off?

Mr. BARK said he supposed that the frontal sinus was cured, and that the case was simply brought to see how easily the sinus could be catheterised.

Dr. HASLAM (Croydon) said he presumed that infundibulum was not as it would be in an old case in which there were secondary changes. It would, no doubt, be necessary to do the radical operation if it were an old case in which there were secondary changes. He would be glad to hear how long the catheterisation had been continued.

The PRESIDENT, in reply, said that when he first saw the case the frontal sinus on that side was patent through the infundibulum, but empty. There was no sinusitis. He mentioned the fact of the antral sinusitis, for which he had done the operation, as being part of the case, but that was not the reason he showed it.

The PRESIDENT showed "An Aural Case for Diagnosis."

Dr. CLAYTON FOX suggested that possibly the case might be one of keloidal formation secondary, probably, to some small cicatrix, which was first started by the rubbing of the hairpin which the patient had been using. It also had somewhat the aspect of a sebaceous cyst, but against that was the fact that it was lobulated.

Mr. McDUGALL (Liverpool) said he thought the case was one of chronic furuncular inflammation, and that dealing with it radically, by thorough scraping, would probably cure it. He did not think it presented the appearance of keloid at all.

The PRESIDENT said his own idea on the matter was that it was possibly a form of external otitis due to some bacterial infection, but there had been no chance yet of making any microscopical investigations.

#### MICROSCOPICAL SPECIMENS.

Dr. WINGRAVE said he wished to remark only on one of the specimens he showed, that of tuberculous cervical lymphatic glands. Of late he had examined a large number of such cases, although he was doubtful as to why they should be called tuberculous. It was true that one found in them giant-cells and practically all the evidence of tuberculosis except the bacillus. The remark would apply equally well to lupus, in which no tubercle bacilli were found. The granulation cells were found in granulomata associated with syphilis, more particularly the tertiary stage, but there were no micro-organisms to be found which were obviously connected with the disease. That specimen exhibited and a number of others he had stained most carefully for evidence of tubercle bacilli, but without success. And on examining those glands, particularly those which were removed before there was any sign of suppuration, there was no sign of any definite character of tubercle; there were simply hard dense masses of epithelioid cells, and a certain amount of interstitial fibrotic change. Many of those suppurating glands were found terminating in pus, and pouring out large quantities of streptothrix and other organisms, so that there were a large number of so-called tuberculous glands which were not due to tubercle at all, but which presented all the histological features minus the specific organism. So it was likely there might be infection from streptothrix from the tonsils and adenoids from the ear and other channels, which gave rise to the characters of so-called tuberculous glands, but without presenting the respective micro-organisms.

Dr. JOBSON HORNE said that Dr. Wingrave had touched upon a very important subject. Although the difficulty of staining sections to demonstrate the tubercle bacillus was a common experience, he did not think it should lead one to jump to the other extreme and say that the glands so examined were not tuberculous. A similar condition of things was met with in adenoid tissue and post-nasal growths, and in tonsils and, indeed, in lymphoid tissue generally, i.e., there were sections such as that excellent one under the microscope demonstrating giant-cells and all the histological structures of tubercle, but not the all-important bacillus. But it was questionable whether one should say that the bacilli were absent from that section. He thought one should not go further than to state that they were not stained. And the reason they were not stained, although the section had been treated with the most perfect technique, was, for some occult cause, to be found in the action of the lymphoid tissue itself upon the organism. By way of demonstrating whether such a gland was or was not tuberculous, the following little animal experiment would be of interest. A patient had tuberculosis of the temporal bone, and he injected a portion of the tissue into a guinea-pig. In due course a gland adjacent to the site of inoculation enlarged and also more distant glands. He inoculated two pigs with it. One he killed before it had run its full term, and examined the glands. In the largest gland, that next to the site of the inoculation, he was able to demonstrate sections very similar to that shown by Dr. Wingrave, that is to say, having all the histological structure of tubercle but none of the bacilli. The same was true of the other smaller glands. But upon inoculating a third guinea-pig from the first and largest gland which demonstrated no tubercle bacilli under the microscope, he was able to kill that guinea-pig with tubercle and to demonstrate in the animal tubercle bacilli. Therefore he thought it would be more correct to say that one failed to demonstrate tubercle bacilli in a gland rather than to say that they were not present.

Dr. WYATT WINGRAVE demonstrated a syringe for intra-laryngeal injections.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD NOVEMBER 17TH, 1904.

Dr. JAMES BARR, the President, in the Chair.

EXTRACTION OF DOUBLE CATARACT.

Mr. THOS. H. BICKERTON exhibited a female patient

æt. 76, upon whom he had operated for double cataract. Cocaine was first tried, but the patient was so restless that the operation could not be undertaken. A few days later, chloroform was administered and double cataract extraction performed. An uneventful recovery followed, and an excellent result as regards vision had been obtained. Mr. Bickerton said this was the first occasion on which he had performed double cataract extraction at one sitting, and remarked upon the rarity with which it was necessary to administer a general anæsthetic for operations of this nature.

Dr. K. A. GROSSMANN congratulated Mr. Bickerton upon his pluck, and upon the admirable result obtained, but he considered double extraction at one sitting a very risky procedure, and mentioned a case in which he had seen most disastrous results follow.

Mr. W. THELWALL THOMAS read a note on the TREATMENT OF SO-CALLED CONCUSSION OF THE BRAIN. He referred to recent physiological research, which had demonstrated the absence of vaso-motor nerves in the cerebral arteries, the impossibility of producing any effect on the circulation of the brain by applications to the exterior of the cranium, the importance of the cerebral venous pressure, and the control the splanchnic vaso-motor mechanism exercised by acting indirectly through the general circulation. He divided concussion into three varieties: (1) simple concussion, merely a temporary disturbance of pressure equilibrium within the cranium, which is quickly recovered from; (2) severe concussion, which he considered to be simply shock; he deprecated the use of ice-bags in this condition, and mentioned cases in which the continued application of ice had perpetuated the symptoms, and recovery had quickly followed on changing the treatment; (3) Continued concussion, in which he considered contusion of the brain and meninges existed. In this condition unconsciousness quickly gave place to irritability, restlessness, mild delirium, &c. A sedative line of treatment was strongly insisted upon, and for this purpose morphia and chloral were greatly preferable to bromides. The importance of absolute quietness, tactful nursing, and the administration of free nourishment was emphasised. Free purgation was not recommended, as it interfered with rest. On returning consciousness, the administration of iodides was of marked value, many of the so-called after-effects of concussion—clouded intellect, loss of memory, and headache—being thus cleared up. So long as the temperature, pulse, and respiration remained normal, if the patient could be made to take adequate nourishment, the prognosis was good. Long-continued unconsciousness, with paresis, paralysis or coma, indicate cerebral laceration, and a rise of temperature without a corresponding quickening of the pulse and respiration, together with a loss of control of the bladder and rectum, generally indicate severe laceration, and the prognosis is consequently much more unfavourable.

Mr. Damer Harrison, Dr. W. Alexander, Dr. W. B. Warrington, Mr. Rushton Parker, Mr. G. P. Newbolt, Mr. E. M. Stockdale, Professor Sherrington, and the President took part in the discussion.

Mr. ROBERT JONES read a note upon SPINAL COCAINISATION,

which will be found in another column under the heading of "Original Communications," page 563.

Dr. WILLIAM CARTER read a paper on SOME OLD AND NEW REMEDIES.

The main proposition was that medicinal and other agents can often, in an unknown way, so modify cells and tissues as to make a diseased person sound, and not that they merely relieve symptoms, while Nature effects a cure. He illustrated this by mentioning cases in which prolonged and most serious illnesses were arrested and the patient cured by using such old remedies as the liquor sarsæ co. concentratus, mercurial inunction, and vinum antimoniale. He drew attention to the fact that the result of examining 25,500 recent prescriptions adopted in the "Extra Pharmacopœia" showed that not one of these substances was so much as mentioned. He contrasted the opinion expressed on the one hand by Boecker, and on the

other by the late Mr. Allanson, of Leeds, concerning the first of these drugs, Boecker simply dismissing it as useless, while Allanson thought highly of it though unable to explain its mode of action. Among other remedies, succinate of iron in biliary colic, and large draughts of pure water in renal colic, were mentioned, and their utility illustrated by cases. Reference was made to the useful effects on leucocytosis and chronic splenic enlargements by X-rays, and a photograph was shown of a very large and remarkable tumour of the face which was considered to be malignant by all the medical men who saw the patient. An operation for its removal had been recommended, but under X-ray treatment the tumour had, in a comparatively short time, entirely disappeared. Lastly, allusion was made to the contradictory opinions of Schmiedeberg and Ringer on the utility of aconite, the first asserting that "saving its value in neuralgias it can be relegated to the obsolete means of treatment," while the second states that "perhaps no drug is more valuable than aconite," and cases were mentioned showing the extraordinary benefit which the drug is capable of affording in certain conditions of the heart.

Dr. R. E. Kelly, Dr. A. G. Gillan, Dr. F. H. Barendt, Dr. E. T. Davies, Mr. F. Larkin, Mr. T. H. Bickerton, Dr. R. J. M. Buchanan, Dr. C. J. Macalister, Dr. N. Roberts, Dr. O. T. Williams, and Dr. K. A. Grossmann took part in the discussion.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, November 26th, 1901.

### TREATMENT OF VAGINAL GONORRHOEA.

THE treatment of blennorrhagia in woman, says Dr. Daniel, is a problem which has much occupied the practitioner. The difficulties of the treatment are derived, on the one hand, from the special anatomical disposition of the female genital organs, and on the other from the multiplication of the microbe of Neisser in the different segments of the uro-genital apparatus. By its canicular form, by its very oblique direction downwards and forwards, the vagina forms an organ difficult to disinfect. Between the folds of the mucous lining the microbes are concealed in chronic blennorrhagia; they seem to take refuge in these localities, from whence they are ready to reinfect the whole region.

It is true that Brumm denied the primitive infection of the vagina; the microbe would be found particularly in the glandular regions: the vulva, the urinary meatus, and also in large numbers in the os. If that be so it is none the less true that the vagina in gonorrhœa infection is the seat of intense inflammation, constituting the most common form of vaginitis.

In any case, the only way to treat and cure vaginal blennorrhagia scientifically is to attack the microbe where it is found. The treatment should consequently be both vulvar, cervico-uterine, urethral and, above all, vaginal.

In very acute cases at the outset, irrigations (6 quarts of boiled water or a solution of permanganate of potash, 1-10,000), associated with prolonged baths, will be sufficient until the acute stage has passed. At this period the following rapid treatment will be attended with remarkable results:—

(a) The whole region inside and out will be washed with soap and warm water by means of a vaginal brush or a piece of sterilised wool.

(b) Rinsing of the vagina with simple boiled water.

(c) Injection of six quarts of a warm solution of permanganate of potash, 1-4,000.

(d) Plugging of the vagina with five or six plugs of sterilised gauze impregnated with the same solution.

(e) At the end of twenty-four hours the plugs are withdrawn and the injection repeated as before, and followed by fresh plugging. At the end of another twelve or twenty-four hours the plugs are definitely removed.

Such is the treatment in its essential points. It is executed in two sittings at an interval of twenty-four hours. As to the results, in the numerous cases in which he had employed it, the absence of all gonococci was verified by the microscope.

During the following days the irrigation of the vagina by the permanganate solution will be continued two or three times a day (two quarts at a time) to prevent any possible return. At the end of ten or fifteen days, when the vaginitis will be cured, the disinfection of the vagina may be completed by that of the uterine os, the vaginal *cul-de-sac*, the vulva, and the urethra. For this it will be sufficient to paint the parts every two days with a solution of nitrate of silver, 1-100. As to the urethra, a pencil of the nitrate will be introduced and immediately withdrawn every eight days for about a month, when all infection will be removed.

#### TREATMENT OF OBESITY.

*Breakfast, 7 o'clock.*—Cold lean meat, two to four ounces; two drachms of bread, a cup of weak tea without sugar or milk. *10 o'clock.*—one egg without bread. *12 o'clock.*—Roast or grilled meat, two to four ounces without gravy or sauce, green vegetables *ad libitum*, without butter or grease, weak tea without sugar. *4 o'clock.*—A cup of tea without sugar. *7 o'clock.*—Two eggs, green vegetables, one ounce of bread, weak tea.

A walk of half an hour after the principal meals. In this way the patient will have lost twenty-four pounds in twenty-five days. At the end of that time the rigour of the *régime* may be lessened; the quantity of bread may be increased, and the tea may be replaced by a little wine and water, and a little butter may be allowed in the vegetables.

For some months the patients will continue to observe the *régime*, and finally they will have lost from forty to eighty pounds weight, by which the dyspeptic troubles, oppression, and bronchial catarrh from which they generally suffer will have been greatly relieved.

Such is the treatment recommended by Professor A. Robin.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, November 26th, 1904.

At the Medical Society, Hr. Baginsky showed an EXTREME DILATATION OF THE COLON, especially of the sigmoid flexure; along with the dilatation there was atrophy of the wall of this section of intestine. The disease was first described by Hirschsprung. The preparation was taken from a child, *æt.* 10 months, who was admitted with extreme meteorism, and died shortly afterwards. There was probably a congenital disposition to the abnormality. It was only when fecal stasis developed that the condition came about.

The speaker then proceeded to discuss

#### ACUTE RHEUMATISM IN CHILDHOOD.

He had observed a total of 139 cases of articular rheumatism in children. One of his assistants had already published an account of 73 of the cases; there remained, therefore, 66 to report on. Those cases of pure primary articular rheumatism only would be considered, not those in which the joint inflammation was secondary to other infantile disease. Amongst infants at the breast there was no case; between the ages of one and five there were 5; between 5 and 10, 32 cases; and 29 between the years 10 and 14. It appeared, therefore, that the greatest number of cases occurred at the age when the greatest increase in height was taking place, *i.e.*, between 5 and 7 and 11 and 14. His statistics did not show that the disease was more frequent during the colder parts of the year, as 24 cases were admitted in the winter months and 42 in the summer. It could not be determined that heredity played any part, as after inquiries showed that only seven of the patients had

suffered from the disease. In spite of this, however, observation in private practice gave him the impression that hereditary disposition was of importance.

An initial angina, the importance of which had been over-rated, was present only in nine cases.

He distinguished two principal groups of the disease of which one passed off quickly and was readily amenable to treatment, while the other was a malignant form, and ran its course either rapidly or led to cardiac complications, which then became the prominent feature. Both forms might have a strong commencement.

Examination of the blood was mostly negative—nephritis appeared rarely, but chorea on the other hand frequently. At one time various serious complications on the part of the central nervous system were described, but he believed that such cases were really cases of cerebro-spinal meningitis. Chorea developed in a third of the cases. In spite of this, however, chorea minor could not be considered as a rheumatic affection as it came on when there was no rheumatism, and then no explanation could be given for its occurrence.

The occurrence of endocarditis in the course of a rheumatic attack was of special importance. The heart remained intact only eight times, 17 were left after subsidence of the cardiac mischief with an apparently healthy heart, 35 were discharged with unsound heart, and 6 died.

Pericarditis had been of special interest to him. He exhibited a series of curves and diagrams which showed the importance of this disease in relation to the course of the cases; most of the cases ended fatally.

He then showed a number of preparations—widely dilated hearts, the enormous dilatation of which flat-sided or band-like, could not be explained by the endocarditis, but by pericarditis. If children got over the pericarditis for the time, they almost, without exception, died from it during puberty.

In rare cases the articular rheumatism of childhood might become chronic, leading to ankylosis of most or even all of the joints.

Therapeutically, since the introduction of salicin, only one thing had changed, the articular diseases could be treated with success. As regarded cardiac disease, we were as powerless as before. The only things that had proved of any value out of the great array of remedies were ice and potassium iodide.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, November 26th, 1904.  
GALE NORVEGIENNE.

AMICIS relates a peculiar case of itch, or "gale Norvégienne," as he is pleased to designate it, in the case of a child that had come under his care. Why he calls it Norwegian itch is not so easily explained, as the patient was an Italian from Naples, *æt.* 13 rachitic and greatly emaciated.

The whole surface of the body was red between the large rupia crusts universally spread over the skin, resembling in every detail psoriasis universalis. The diagnosis might have been more difficult had Amicis not had the father previously under his care for scabies. On examining the crusts on the child the sarcoptes scabei, or Bergh's acari, was discovered by the microscope, which confirmed his opinion of its being the Norwegian disease.

#### HYDROPHOBIA AND INOCULATION.

Heydenreich tells a fine story of how two persons were bitten by a dog which was supposed to be mad. To confirm the opinion the dog was taken to a veterinary surgeon and duly killed, but, strange to say, no *post-mortem* examination was made of the dog, nor the membranes of the brain. Pasteur's preventive lymph was inoculated in one of the cases, while the second refused the "saving grace."

After the inoculation, the patient, who had every confidence in the wisdom of his medical man, was taken ill with a high fever, great pain in the bowels with intractable constipation. Shortly after this, paralysis, with a severe form of psychosis, made its appearance.

At this stage of the disease Heydenreich saw the patient and declared that some mistake had arisen, as the whole train of symptoms were not in accord with the recognised descriptions. The mad dog was exhumed and examined, but no condition of the membranes could be found resembling "wirt." It was therefore concluded that the symptoms were due to the lymph and not to any poison from the dog, as the second party bitten by the dog, who refused the treatment, remained perfectly well, and smiled at his fellow's credulity!

#### HEMATIC CONCENTRATION AND NEPHRITIS.

Loeb and Adrian have recently been experimenting with the molecular concentration of blood and its effect on the kidneys. They find that it is only in bilateral nephritis that this concentration of the blood takes place. Blood freezing at the normal point, therefore, may cause functional disturbances, or morbid conditions of the renal tract anywhere in the kidney affected, but never when both kidneys are involved. He considers this test pathognomonic of bilateral nephritis, and easier applied than testing the urine from the individual ureters.

#### THERMOPALPATION.

Sommer in his investigations reveals a state of temperature which may have some bearing on the therapeutics of the ear. In using Herz's thermopalpation instrument he has come to the conclusion that both of our ears have not the same temperature; that the left ear cavity has a higher temperature than the right. The difference is not great, but sufficient to be distinctly observed by the instrument. He concludes that this high temperature is due to a more active condition of the left side of the brain, where the circulation is greater in the left hemisphere than the right.

#### SYPHILIS AND MERCURIAL VAPOUR.

Welander, of Stockholm, writes to the *Wachenschrift* his experience of the vapour treatment of syphilis in females, which he prescribes in measured quantities for inhalation. He finds this form of administering mercury admirable for children suffering from hereditary syphilis. The urine must be carefully watched for albumin and cylinders, which frequently supervene. This treatment requires special wards, which have now been in existence in that city for the last four years, and have been instrumental in saving many children that would have inevitably died if left in their own homes. In Sweden syphilis is not so widespread as in many other countries, as all persons so affected are taken into hospital and carefully treated till all trace of the disease has disappeared. This is one of the causes assigned for the low number of cases to be found in that country.

#### ACNE VULGARIS.

Söllner finds a large number of micro-organisms in acne vulgaris, but there is not one among the number that could be cited as the etiology of the disease.

#### IS TUBERCLE INHERITED?

Schmorl and Zeipel have devoted a great deal of time to the examination of the placenta in order to determine the absence or presence of tubercle in membranes of the offspring. They give a long history of twenty cases. One of miliary tuberculosis, one of tuberculous meningitis, eleven of advanced tuberculosis, four of fully developed and three of incipient pulmonary tuberculosis. In nine of these cases tuberculous changes were present in the placenta. It requires careful manipulation to discover the morbid product, as may be inferred from 2,000 sections being necessary in one case. The tuberculous centres are usually located to the outer shaggy surface or the inner; more rarely on the decidua basalis, and least of all on the broad chorial surface of the placenta. By this it is argued that tuberculosis can be directly transmitted without infection at all.

## The Operating Theatres.

### ST. PETER'S HOSPITAL FOR STONE.

#### REMARKS ON LAST WEEK'S CASE OF PROSTATECTOMY.

—Dr. THOMPSON WALKER pointed out that the questions of practical importance in regard to prostatectomy are: What is the risk of the operation? How long will it be before the patient is well? And what are the after results? He said that recently (*Practitioner*, August, 1904) he had collected 83 cases of suprapubic prostatectomy by various surgeons and found that the total death-rate of the operation, both immediate and during convalescence, was 10.8 per cent. This included some cases in which the fatal result was not directly due to the operation, but as it occurred before the patient was completely recovered from the operation these deaths had to be counted as part of the mortality of the operation itself. Taking this death-rate as it stands it is an astonishingly low figure; for it must be remembered that the average age of these patients was 65 years and 8 months, while 22 of them were over 70 years of age, and 79 per cent. of this total number of cases were over 60 years. On tabulating the ages with the deaths he found, however, that the risk did not increase with the age. The risk is, of course, greater where advanced kidney disease, bronchitis, or such complications are present, but even in such cases the patient need not be refused operation, for many of the successful cases had been suffering from these and other serious complications. When this mortality is compared with that of other operations of equal gravity, it will be seen to be very small. The duration of convalescence varies a good deal. A few cases may be healed and out of the surgeon's hands in three weeks, but some take double that time. The average is, he thought, about four or five weeks. By this time the suprapubic wound is healed, and the patient is well enough to leave the surgeon's care. The recovery of vitality and general health in these patients is remarkable, and it is the more striking the more depressed the general condition was before the operation. The risks of the operation extend, however, through the whole course of the convalescence, and there are few operations he knew of in which the anxiety of the surgeon is more prolonged. In the series of cases he collected, death occurred as late as the twentieth and twenty second days after operation. In a case of his own the patient progressed without any unfavourable symptoms, except delayed healing of a very thick abdominal wall, until the end of the fifth week, when he began to lose ground, and died six weeks after the operation, apparently from septic absorption. The complication of sepsis he considered to be one of the most important the surgeon has to fear, and it is difficult to guard against, for many of the bladders operated upon are in a state of chronic cystitis and the urine is foul. Prolonged preparation by bladder washing previous to the operation is not always possible, although it is very important in these septic cases. Nor is it always effectual, for the bladder often contains pouches and calculi may be present. Urethral drainage through a catheter is imperfect, and perineal drainage is little better. Suprapubic cystotomy in such cases is attended by too high a mortality to be lightly considered as a preliminary measure. He thought the best preparation was prolonged careful bladder washing

by the urethra. The after-results of prostatectomy as it is now practised in this country are very surprising and completely controvert the statements of the great surgeons of the last generation, that the bladder function was destroyed and would not be regained even if the obstruction were removed. These patients retain their urine as long, and pass it in as powerful and free a stream, as they did before the prostate began to obstruct the outlet of the bladder. The result of the operation is therefore perfect. There is no incontinence, no fistula, and there is no stricture. The two former sequelæ may be noticed in the records of cases done by the perineal method. He referred especially to the cases reported by Continental surgeons, who have told him personally that such results are far from uncommon. The possibility of stricture has been more than once raised as an objection to this operation. Experience has shown that such fears are groundless.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, NOVEMBER 30, 1904.

#### THE ANNUAL MEETING OF THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

THE times have changed at the annual meeting of the Fellows and members of the Royal College of Surgeons, England, as may be gathered by the fact that on the 17th inst., when the meeting was held, the proceedings had to be suspended in consequence of the necessary quorum not being present. As far as we are aware no such incident has ever occurred before; on the contrary, the occasion has always been one on which many members have availed themselves of the pretext to visit their College, and by their presence support those who had made themselves the leaders of what used to be known as "college politics"; there is, however, no gainsaying the fact that at the present moment so-called "college politics" are at their lowest ebb. The Association of Fellows, which represented the Reforming body of Fellows, has ceased to exist; and the Association of members, if it has now any political existence, is not taken

seriously; and thus it has come to pass that despite the fierce engagements which in former years took place between the Council and the "body corporate" the lapse of time has converted the sword into the ploughshare, and the Council reigns serenely as of yore, secure in its traditions and just as unassailable. Still, it is interesting to recall that the present President owed to the suffrages of the Reforming body of Fellows his first election into the Council. At the time in question he was an active member of the former and lost no opportunity of impressing upon the Council the necessity of granting concessions in favour both of the Fellows and members. It was soon after his election that the career of real political importance of the Association of Fellows began. Its candidates at the annual election of members of the Council were then nearly always successful; the Association, in fact, had attained a degree of organisation which constituted it a real menace to the old time conservatism of the Council. The Council were thus compelled to recognise its political importance, earnestness, and influence, and then it was that certain reforms were granted from which the Fellows have since benefited. So far, however, as the meeting on the 17th instant is concerned, we are glad to note that the business transacted thereat consisted of several important matters apart from college politics. Nothing, for example, could have been more in keeping with the character of the meeting than the resolution moved by Dr. Danford Thomas, having reference to the relations of the medical profession to the Coroners' Courts. It is unnecessary to point out why this has become such a burning question of the day, inasmuch as the facts are notorious in connection therewith. Nevertheless, when the matter was referred by the London County Council to the Council of the College no steps were taken to prepare an exhaustive report thereon, nor was any authoritative attempt made by the latter to indicate the strong feeling which existed in the profession against the irregularities which had occurred in one particular Coroner's Court. We entirely agree with Dr. Danford Thomas that the Council of the College, instead of acting in an invertebrate manner, would have done well to have arranged an independent inquiry into the matter with the assistance of some Fellows and members having intimate knowledge of the subject. We hope that even now some means may be found by which the College, may exert its influence by the expression of an authoritative opinion upon the irregularities which have occurred. As a member truly pointed out according to Bye-law XV. of the College the College promises at all times to protect and defend the Fellows and members in the exercise of their rights, and in our opinion this is precisely the occasion on which the Bye-law in question might usefully be carried out.

#### THE HOSPITAL FUNDS AND THE SMALL HOSPITALS.

NOT unnaturally the publication of our recent

leading article dealing with the policy of the Hospital Saturday, the Hospital Sunday, and the King Edward's Funds towards the small metropolitan hospitals has attracted considerable attention. Our main contention was to the effect that whereas the institutions in question were supported by the Saturday Fund that many of them, on the other hand, sustained serious damage in loss of prestige and of income, owing to their non-recognition by the other two of the above-mentioned funds. The Editor of the *Hospital*, an acknowledged authority in the world of medical charity, has entered a temperately worded tentative protest against our position and has asked for a list of excluded small hospitals. He points to the fact that the grants to the thirty-three small hospitals have materially increased during the past few years. That argument by no means disposes of the claims of the small hospitals that happen to be outside the charmed circle of favoured institutions. It is much the same as saying that because the Registrar-General has devoted more care to the statistical returns of the thirty-three great towns of England and Wales, therefore other insignificant towns left out in the cold should rest and be thankful. We venture to suggest to Sir Henry Burdett, however, that the alleged injury to the small hospitals not included among the recipients of grants from the King Edward's and the Hospital Sunday Funds is in no way mitigated by his pointing to the thirty-three small hospitals that have been so favoured and recognised. Indeed his statement merely serves to emphasise the inequality of distribution and to invite an inquiry into the principles that prompt the Committees in making their awards. In an early issue we hope to furnish Sir Henry with the desired list of small hospitals that have been excluded from the benefits of the two Funds in question. Meanwhile it is only fair and right that the public who contribute the money should be fully and exactly informed as to the precise principles upon which the grants are allocated. So far as it is possible to form a judgment from results the wisdom of the controlling Funds is not altogether self-evident. Take the case of the Royal Orthopædic Hospital, which until recently stood upon an enviously valuable site in Oxford Street. Some years ago the then executive, under the chairmanship of Sir Walter Gilbey, wished to sell the site; but their scheme was not approved by the Governors, and Sir Walter was succeeded in the chairmanship by Mr. H. H. Marks, the well-known financial magnate and now M.P. The newly-elected executive again determined to sell, and that course was urged by the Sunday Fund in the most forcible way at their command—namely, by withholding a grant until amalgamation or sale of the Royal Orthopædic Hospital had been effected. Meanwhile the opponents of the scheme for sale did not relax their efforts, and although they did not succeed in preventing the sale, they nevertheless raised the selling price by no less a sum than £12,000. Now the Sunday Fund had urged the Hospital to sell at the lower price, so that if the advice of the Fund

had been followed twelve thousand pounds would have been lost to the charity. Now we think the public is entitled to know on what grounds the Hospital Sunday Fund urged the sale of the enormously valuable site in Oxford Street, not only at the lower price, which was clearly far under the actual value, but at any price at all. What ordinary citizen of any business capacity would have dreamed of parting with a valuable freehold in order to spend the purchase money in building another hospital on leasehold property elsewhere? We are entitled to ask if the Hospital Sunday Fund, before assuming this great responsibility with regard to urging the sale of the Orthopædic Hospital premises, made itself fully acquainted with the arguments of the minority opposing the sale. There is no need to remind Sir Henry Burdett of the history of the dispute in question, with the details of which he is already acquainted. We should be glad to hear his explanation of the part played by the Hospital Funds in the sale of the Royal Orthopædic Hospital site. We shall be also glad to learn what evidence was taken for and against the proposal. In short, this case may be taken as a preliminary opening up of our inquiry into the methods that control the Hospital Funds. His Majesty King Edward, as we said on a previous occasion, will be the first to insist upon the correction of any inequality of administration that may be revealed. We may commend to his gracious consideration as a first step towards security of justice the proposition that every hospital, regardless of its size, should be represented upon his own and upon the Hospital Sunday Funds, as in the case of the Saturday Fund.

### Notes on Current Topics.

#### Spinal Anæsthesia in Labour.

SINCE the fall of our first parents it has been the lot of womankind to bring forth children only at the cost of much suffering to herself, and the inventor of a method by which that process could be accomplished without pain would deserve, and probably receive, the benediction of a host of mothers. Martin has been trying whether the production of local anæsthesia by spinal cocainisation would not be as serviceable in labour as it is reported to have been in a large number of surgical operations. In all he has employed the method in thirty cases, his usual plan being to inject a centigramme of a 1 in 2,000 solution of adrenalin into the subdorsal space, and to follow this five minutes later by a solution of cocaine. The effects were not all consistent, but although marked variations occurred in the duration of the action of the drug, in twenty-nine cases good anæsthesia was obtained. In nine of these cases it lasted only half an hour, but in most of the others it persisted from one to three or even four hours. When labour came on within an hour or an hour and a half after the injection, the pains were but little felt by the mother, but in all cases the uterine contractions were retarded, and the patients used their abdominal muscles only when urged to do

so. The majority of the patients had marked vomiting and nausea after the injections, an effect that was not counteracted by the subsequent injections of caffeine salicylate, as Martin had expected. This, however, seems to have been the worst that happened, for the puerperium was not disturbed and milk secretion was natural. Martin, at any rate, is so far pleased with his plan that he proposes to continue it in further cases where chloroform is inadvisable. We should be glad if he could so far perfect the operation as to make the birth of a child no more of a burden to a healthy, civilised woman than it is at present to a negro woman in Central Africa; but we fear that such a consummation is more to be wished for than expected.

#### Figs as Physic.

THE generous amplitude with which the British Pharmacopœia is recruited from the vegetable world is recognised mainly by students of therapeutics. From every quarter of the globe, from every herb that bears fruit and those which do not, some active principle may be obtained, if only man's ingenuity can find it out. Many of these products, from the stately tree of the forest to the humble weed that flourishes in the ditch, are of distinct use "for the healing of the nations." The therapeutic value of the fig has been recognised from remote ages. As an article of food it was largely used by both the Greeks and the Spartans, while an alcoholic beverage prepared from the fermented fruit was known to Pliny under the name of *scytis*. The so-called seeds, which are in reality the fruit proper contained within a fleshy receptacle, have long enjoyed a reputation as a mild laxative, and to this day the fig itself, green or dry, or syrupy preparations thereof, are consumed with this object. It is somewhat strange, however, that this popular remedy only receives the sanction of the Pharmacopœia as one of the ingredients of that most comfortable electuary, *Confectio Sennæ*. The receptacles when cut open act admirably as a cataplasm, the knowledge of their heat-retaining properties as adapted to the treatment of boils being at least as old as the days of Hezekiah. In virtue of the sugar which they contain, such an application would be quite as antiseptic, if not more so, as the more familiar linseed-poultice. A syrupy extract of figs has also been recommended as a demulcent in certain irritable affections of the throat. The juice from the stems and leaves of the *Ficus carica* is acrid and it has been employed to raise blisters. The fruit enters largely into the dietary of the nations of Southern Europe, and an attempt is being made in certain quarters to institute a "cult" for the more general consumption of the fig in this country.

#### Weight-carrying and Growth.

THE adaptation of the skeleton to the strain imposed upon it while lifting or carrying heavy burdens is no less surprising than the amount of muscular strength exhibited by those who are daily accustomed to such tasks. Physical endur-

ance is by no means invariably commensurate with great muscular development, but there is no disputing the fact that feats involving Herculean strength can only be performed by persons whose muscular tissue is powerfully knit together. Mere bulk alone is, of course, no criterion whatever of muscular strength, as may be readily proved in the case of that curious affection, pseudo-hypertrophic paralysis. It is the fitness of each individual fibre and its ability to contract co-ordinately with its fellows in response to its owner's commands which constitutes real muscular efficiency. As far as lifting heavy weights is concerned, everyone knows who is accustomed to such work that there is a good deal in getting hold of the load in the right manner and also in the method by which it is supported by the body. In other words, knack is almost as important as muscular strength, a fact to which any railway-porter can testify. The head and shoulder are the best anatomical sites for weight-carrying, and it has been shown that characteristic bony change may ensue after an individual has been engaged in this work for a number of years. The worst position is that in which the weight is held in front of the trunk and the body consequently bent backwards, the head being flexed. A good deal of strain is thus imposed upon the abdominal muscles, and if the abdominal rings are abnormally patent there is a risk of a hernia coming down. The dwarfing effect of weight-lifting upon young girls was dwelt upon by Miss Anderson, Chief Lady Inspector of Factories in her evidence before the Physical Deterioration Committee. Heavy lumps of clay are sometimes carried by girls in their teens, and loads of fruit are similarly borne in certain jam factories by young women. It is most desirable that a general maximum of weight that may be handled by young persons should be legally established for all industries alike.

#### Light as an Anæsthetic.

ONE might have been pardoned for believing that most of the uses of light had already been explained within recent years. Red light, white light, the ultra-violet rays, and so on, each was stated to have its own sphere of usefulness in therapeutics or in diagnosis. If we are to put faith in some recent reports, however, blue light has a peculiar power of its own, in that it is said to produce anæsthesia. Professor Redard, of Genoa, has published several cases in which he states that he produced brief periods of excellent surgical anæsthesia by the simple device of making the patient fix his gaze on an intense blue light. The apparatus used is simply an electric arc lamp enclosed in a blue globe, and fixed in a blue polished reflector. The patient's head is covered by a blue cloth in such a way as to shut out all rays of light but those coming from the lamp. He is instructed to keep his eyes open and fixed on the light, and Professor Redard states that in two or three minutes the pupils become widely dilated, and anæsthesia exists. It persists long enough to permit of such an

operation as extraction of five or six teeth, and the patient is quite unconscious of what is being done. Redard does not regard the phenomenon as hypnotic, for he has failed to produce it by suggestion, or by the use of any other light than blue.

#### The Cause of Rabies.

It is curious that some of the diseases in regard to which we have been most successful in the production of artificial immunity depend on causes of which we are still ignorant. This is true both of small-pox and of rabies, for although in the investigation of these diseases many bodies have been given by their discoverers a causal importance, yet up to the present there is no general agreement in either case. In regard to rabies, most interest at present centres round the researches of Dr. Legri, of Pavia, who last year described certain bodies found in the nervous system of animals dead of rabies. The bodies are round in shape, and vary in size from what can be just seen with the highest power of a microscope up to a diameter of twenty-five microns, the average size being four to ten microns. They were found in all parts of the nervous system, and can be demonstrated by the ordinary stains. Legri himself found them present in fifty out of fifty-two cases examined, while he has never seen them in any other condition than rabies. His observations have been confirmed by several Italian investigators of repute, and though the case is far from proven, yet there is on the face of it nothing against Legri's belief that he has discovered the organism of rabies.

#### A Hospital for the Insane.

VERY slowly, but it may be hoped surely, the idea is beginning to filter into the minds of administrators of the Lunacy Acts that a mentally-affected man is not merely a useless unit in society for whom a pigeon-hole has to be found to keep him out of harm's way, but a sick person who needs treatment. The accurate diagnosis of mental cases is as important as that of physical ones, and the consequent classification with a view to remedial treatment should be the foremost consideration in all lunacy administration. The chief function of diagnosis should be to separate the curable from the incurable, and the former should be considered so distinct a class from the latter that they should have no communication with them in the asylum. The ideal arrangement would be to have the patients susceptible of cure housed and looked after in separate establishments, but though it will be necessary to wait long to see such a desirable consummation, we are glad to note in the report of the Asylums Committee of the London County Council that a step in the right direction is to be taken. At the Bexley Asylum it is proposed to build a "villa," containing accommodation for fifty male patients, where cases capable of amelioration or cure will be placed, and from which any patient deemed incurable will be drafted to the main asylum. Already a similar villa is in working

order on the female side, and the arrangement has proved most beneficial, for it has proved that the bulk of the new cases need never enter the asylum proper at all. After discharge from the hospital villa cases will be transferred to a convalescent villa, and kept there till able to re-mingle with their sane fellows in the world once more. Hospital as opposed to asylum treatment of mental diseases, especially for mild and curable cases, will be a great advance, and hand in hand with it should go increased facilities for the study of mental diseases. The Asylums Committee of the London County Council are certainly waking up; it may be hoped that they will not be tempted to turn over and go to sleep again.

#### Repetition of Prescriptions.

WE have at various times commented on the danger to the public which is the result of the undue repetition of prescriptions. To cite no other example, it is obvious that the presenting time after time of an old prescription may make the path easy for the victim of a drug habit. In order to attempt the solution of a problem which not only by medical men but by pharmacists is recognised to be urgent, a conference has recently been held between representatives of the British Medical Association and of the Pharmaceutical Society. It is to be hoped that a friendly discussion of this sort will lead to some settlement agreeable both to the physician and the dispenser. In the meantime, certain suggestions are to be sent for consideration to the divisions of the British Medical Association, which, if adopted by a large body of the profession, and supported by dispensing chemists, will go far to check the evil. They are that every prescriber should signify in his prescription the maximum number of times it may be prescribed, and that he should also sign it with his full name and address. Any real solution must depend, however, on the hearty co-operation of the pharmacists throughout the country with the medical profession.

#### Detention of Medical Witnesses.

THERE are few medical men who have not, time and again, been dragged into court to give evidence in a case for a fee of a few shillings, and been kept waiting for many hours during which their ordinary work was urgently demanding their presence. It is, of course, inevitable that medical men, as part of their duty to the State, should give evidence in criminal cases, but they have a right to expect that the State in return will consider them and their patients in every possible way. Such, unfortunately, is far from being the case. The object of solicitors is to have their case ready and their witnesses present in good time, and the language in which subpoenas are couched makes the absence of any witness so serious an offence that it is generally unwise to risk not being available when a case is called unexpectedly. But the want of thought in this matter on the part of many solicitors often amounts to an abuse of their powers, and we

are glad to see that Mr. Justice Grantham warmly espoused the cause of professional witnesses at the recent sessions at the Old Bailey. The Judge said that he had received many complaints from medical men about the way they were summoned day after day when their services were not in the least likely to be required, and he was bound to admit that in his opinion the complaints were well justified. Cases, he said, were put into the lists when there was no chance of their being called, and the medical men engaged were kept kicking their heels about the court at great detriment to themselves and their profession. He impressed on counsel the duty of keeping the clerk informed of the length of time cases were likely to last, and on solicitors of finding out when their cases would be reached, and on both the importance of obviating inconvenience to medical men. It is refreshing to hear of a judge standing up for the much-trying doctors, and we hope his words will be taken to heart by the officials of other courts besides that in which they were spoken.

#### Repeated Rupture of the Uterus.

THERE is no accident occurring in child-birth which is regarded as more serious than rupture of the uterus, especially when it is complicated by passage of the child into the peritoneal cavity. It is luckily a rare occurrence, and does not happen if the patient is under proper observation. When it does occur, however, prognosis is bad for both mother and child. The child usually dies immediately, and the mother is likely to succumb to the effects of hæmorrhage and shock, or, if she rally from them, to general peritoneal infection. A case recently reported, therefore, by Patz, of Vienna, is all the more remarkable in that rupture occurred twice in the same woman, with an interval of five years, and the patient still survives. On each occasion a laparotomy was performed and a dead child extracted, and the uterine wound repaired. The first rupture took place in the anterior wall of the cervix and vagina, and the second through the posterior wall, the old scar remaining firm. The woman had a contracted rickety pelvis, and in order to prevent her increasing her already remarkable record, Patz accompanied his second operation by a hysterectomy.

#### Revivalism.

THE curious wave of revivalism that is now passing over some parts of South Wales illustrates the power of personality in a remarkable fashion, especially when that personality is animated by an intense and conscious prepossession. A Mr. Evans Roberts, a young working collier, is conducting a series of services in various villages at which extraordinary manifestations of enthusiasm and loss of self-control are witnessed. The audiences assemble long before the appointed time of meeting, and immediately the doors open the chapels are crammed to suffocation. Hymns, prayers, and addresses from Mr. Roberts go on for hour after hour, till strong men fall on the floor,

confess their sins, and weep on each other's necks like women. Some of these meetings last half the night, and others begin at three in the morning. Everywhere the same excitement prevails, and there can be no doubt about the depth of the impression produced at the time. The interesting point is that Mr. Roberts himself is by no means a good speaker; many of his hearers are known locally to be far better orators. Moreover, usually the key-note of his meetings is said to be merriment, Mr. Roberts smiling as he prays, and laughing as he preaches. But he has a vivid idea of his mission, and believes himself inspired by a Supreme Being "which put its hands on his shoulders and bent him double till the blood rushed to his head." The imitative influence of many hysterical affections is illustrated in this particular instance by the fact that at one meeting he fell on the floor whilst praying and continued his supplication in the prone position. One after another his audience proceeded likewise to fall on the ground and begin praying aloud. The psychological disposition of a crowd is an interesting study, for the effect of suggestion is much more easily seen in a mass of people together than in a single individual, and the power of affecting crowds of people till they lose self-control is given to but few individuals. One thing certain is that Mr. Roberts' campaign cannot go on for ever, and his health is sure to be undermined by these long drawn-out periods of excitement and abstinence from food, whilst there are worse dangers than mere bodily fatigue likely to be incurred by those who attend revival meetings.

#### History of Syphilis.

SOME interesting information is brought together by Dr. Knott, in the current number of the *Dublin Journal of Medical Science*, with regard to the early history of the disease and the word "syphilis." He tells us that the word was first used in 1530 as the title of a poem by Hieronimo Fracastorio, a native of Verona. This astonishing poem, which describes what was then thought to be a new disease, fills a quarto book of thirty-six leaves, and is highly praised by many critics from Scaliger to Dr. Knott himself. The latter is not a believer in the doctrine that syphilis was first introduced to Europe by the sailors of Columbus, and he brings much evidence to show that it existed long before, though there is no doubt, of course, that its great prevalence in modern society dates from the Siege of Naples in 1494. From its devastation of the French army at that time it obtained the well-known name "*morbis gallicus*," though the French themselves called it "*morbis neapolitanus*." Indeed, there were many national names given to it in different countries, as, for instance, "Spanish itch," "German," "Polish," "Turkish," disease, while the Turks responded with the name "Christian disease." From its similarity to the physical affection of Job, it has been known as "*morbis sancti Jobi*," and certain saints—St. Mevius, St. Roch, and St. Lementius—have also had the discredit of giving it a name.

### Occupation Pains.

It is noteworthy that many symptoms of disease and even some physical signs are causally associated with certain occupations. The more or less continuous assumption of a particular attitude, as writing, sewing, or digging, or the habitual exercise of the same group of muscles, as in handling certain tools, cannot fail, after a time, to leave its mark upon the body and some times even upon the bony skeleton. This latter point has been elaborated by Mr. Arbuthnot Lane, who has found that considerable changes may and do occur in the osseous framework of the body as a result of an alteration in the manner in which lines of force are transmitted through one of its segments. These changes are chiefly of anatomical and pathological interest. From the subjective point of view pain of some kind or other is nearly always a prominent feature wherever there is unnatural or persistent strain to be borne. The stooping posture at work is one of the commonest deviations from the normal, and whether the patient be a seamstress or a coal-heaver, a city clerk or a market-gardener, each and all are liable to suffer from a twisted chest and a crooked back. Among resulting ills are dyspepsia, a tendency to bronchial troubles and phthisis, backache, sciatica, and lumbago. Different occupations must necessarily give rise to varied symptoms which are due to the particular kind of work undertaken. The expressions "occupation-neurosis" and "occupation-dermatitis" are in common use, but we do not hear so much about "occupation-pain." Dr. James J. Walsh, of New York, read a paper upon this important subject before the recent meeting of the State Medical Association, in which he stated that many of the aches and pains in reality caused entirely by the individual's work were erroneously supposed to be due to chronic rheumatism. The fact remains, however, that the majority of such pains are decidedly aggravated by cold and damp.

### Hygiene as She is Wrote.

THE desirability of including teaching in the elements of hygiene to youngsters in elementary schools has been considerably to the fore of late, and it is encouraging to know that in some schools instruction is already being given. But it is one thing to give instruction and another to receive it, and the examiner is likely to be relieved of a good deal of the tedium that usually attaches to his office if pupils in general are as naïf as those whom Dr. Newsholme recently had the pleasure of testing in hygiene and first aid. One boy had so firmly grasped the principles of sanitation that he was able to reply to a question that "the best way to avoid danger from impure water in the cistern—is to have water from the main sewer in the road in front." Such a youth ought to run but little risk of typhoid fever in after life. The treatment of dog-bites seems to have taken a firm hold on the pupils, and amusing as the answers are, they point to instruction of a somewhat archaic type having been instilled into the young brains. "It should

be burnt out with a cosmetic," wrote one hopeful—a procedure a good deal more humane, and not much less appropriate than the one he intended to describe. A laconic fellow-student answered the same question with "Red-hot poker," without mention of extenuating circumstances. His teacher must, we fear, have been of what the homœopaths call "the old school"; at any rate one would be inclined to give both teacher and pupil a wide berth if one happened to have been bitten by anything but a very rabid dog. But the answer at once most humorous and least open to cavil was that of a young gallant, more circum-spect than altruistic, who suggested, "If any person is found handy and foolish enough to suck the bite, let it be done." There is a fine air of detachment about this, which makes us fear that the spirit of the Good Samaritan had not imbued the little author with the nobility of his calling.

### A Parisian on American Surgery.

DR. FAURE, the well-known Paris surgeon, has recently paid a visit to America, and on his return to France has published the result of his observations. He was particularly astonished at the magnificence of some of the operating-rooms in the New World, and he mentions the Mount Sinai Hospital, New York, as the handsomest he has seen. Both walls and ceiling are formed of single sheets of white marble, and M. Faure naturally regards such opulence rather as a mark of prodigality than as justifiable expenditure. The number of assistants and nurses present at an operation—three or four of each—is in contrast to what obtains in France, where the surgeon aims at performing his work with the aid of only one assistant. What seized M. Faure's admiration more than anything else was the excellent and intelligent nursing across the Atlantic. The American nurse is usually a young woman of good education and social standing, quite different from the French *infirmière*, and tasks are entrusted to her which in Paris are the duty of the *internes*. American surgical instruments appeared clumsy and coarse to one used to the neatness of the hand-made articles in use in France. While M. Faure, like another observer, thinks that there are some matters they order better in France, yet he is, on the whole, an appreciative critic of American surgery.

### Carbonic Oxide Poisoning.

THE risks run by factory workers in lime kilns, cement works, and other places where braziers' and coke fires are employed in confined spaces from the inhalation of carbon monoxide are notorious. Milder degrees of poisoning by that gas, however, are often overlooked. Insufficient ventilation of workrooms and defective gas-fittings, for instance, whereby small quantities of the gas are continuously and imperceptibly inhaled for many hours daily, induce a condition of chronic anæmia which in its turn leads on to something worse. A memorandum upon the use of water-gas and the consequent danger of

poisoning by carbonic oxide has been issued by the Chief Inspector of Factories. In the annual report of the Factory Department during the five years 1899 to 1903 fifty-one cases of poisoning by water-gas are detailed. Seventeen of these were directly due to carbonic oxide, while thirty-four were due to gases of a similar nature, such as those of Dowson and Mond, employed for heating furnaces, boilers, and for other industrial processes. Many different causes contributed towards the casualties, such as ignorance of the nature of the gas, cleaning of flues before a sufficient time had been allowed for the gas to escape, lack of rescue appliances, and so on. It is recommended that notices of warning be posted up in factories and workshops where any danger of this nature exists, and it is to be hoped that the instructions contained therein will be carefully followed. The value of a knowledge by the master and foremen of a factory of the principles of first aid, especially of the methods of performing artificial respiration, should certainly be more fully recognised, as it is only by the prompt application of remedial measures that life can be saved. The stability of the combination of carbonic oxide with hæmoglobin is well known to chemical physiologists, and this being the case there is all the more urgent need for immediate and energetic treatment.

#### PERSONAL.

DR. C. THEODORE WILLIAMS will preside at the Sixth Annual Dinner of the Medical Graduates' College and Polyclinic, to be held at the Trocadero Restaurant, London, on December 7th. Further particulars can be obtained of the Hon. Sec., Mr. A. E. Hayward Pinch, F.R.C.S., 22, Chenies Street, W.C.

PROFESSOR ARTHUR THOMSON, M.B., who holds the chair of Human Anatomy in the University of Oxford, last week formally took his seat on the General Medical Council as representative of this University.

AT the same meeting of the General Medical Council Dr. A. G. Barrs was introduced as the member representing the University of Leeds for three years from October 19th, 1904.

DR. ARTHUR G. BOYCOTT, Fellow of Brasenose College, Oxford, Gordon Lecturer in Experimental Pathology at Guy's Hospital, has been appointed Assistant Bacteriologist at the Lister Institute of Preventive Medicine.

SIR JAMES RECKETT has made a handsome donation of £6,000 to the Hull Royal Infirmary for the purpose of completing the extension of the buildings of that Institution.

THE Lady Cheylesmore, Mayoress of Westminster, has kindly consented to open the new building of the Royal Ear Hospital, recently erected in Dean Street, Soho, on Monday, December 12th, at 3 p.m.

DR. L. V. DUBOIS, Government and Poor law Medical Officer of Pampléousses, Mauritius, has been appointed Government Medical Officer, Savanne. Dr. L. de Boucherville takes the place of Dr. Dubois at Pampléousses.

PROFESSOR FRANCIS DIXON, M.D., delivered an address on the "Distribution of the Peripheral Nerves" at the opening meeting of the Dublin University Biological Association on Thursday last. Amongst the speakers who followed him were Professor J.

Symington, M.D., F.R.S., Professor W. H. Thompson M.D., Dr. A. R. Parsons, and Mr. T. E. Gordon F.R.C.S.

DR. ROBERT PUGH, assistant medical officer at the London County Asylum, Claybury, has been appointed medical superintendent to the Brecon and Radnor Lunatic Asylum.

### Special Correspondence.

[FROM OUR OWN CORRESPONDENT.]

#### SCOTLAND.

REPORT ON EDINBURGH DISTRICT ASYLUM AT BAYGOUR.—Dr. Frazer's report on the Asylum, which has but recently been opened, is of an entirely favourable character. Since June 1st, 182 patients have been admitted; their condition is highly satisfactory, and there has been no employment of seclusion or restraint in the treatment of any case. The employment of the patients is exceptionally well attended to, 66 per cent. being engaged in useful work, mostly on the farm, garden, or grounds, showing that full advantage is being taken of the benefits afforded by the abundance of outdoor labour possible on the Asylum estate. The day staff is in the proportion of one to nine, and the night staff of one to thirty-six patients. The permanent buildings—administrative, laundry, and superintendent's house—are well advanced in progress. The capacity of the reservoir, which is nearly completed, will be nearly 13½ million gallons, which will be adequate for all future needs. The following statement shows the number of pauper lunatics in the Edinburgh parish in 1894 and 1904:—

Year.	Royal Asylum.	Poor-house.	Other Asylums.	Private Houses.	Total
1894	346	79	6	310	741
1904	389	234	169	294	1,086

The percentage in private dwellings is 27.1, which is much higher than that in any other urban parish in Scotland.

CHALMER'S HOSPITAL, EDINBURGH.—This institution will be reopened on December 1st, after having been closed for several months while undergoing structural alterations to bring it up to the requirements of modern surgery. As stated in this column some months ago, it is an endowed non-teaching hospital partially free, partially for paying patients. The charges for the latter are very moderate, and this part of the hospital has always been fully occupied. The chief alterations made during the summer consist in the removal of the out-patient department from the main building to a structure formerly used as a laundry, which has now been reconstructed so as to include a waiting-room, consulting-room, small theatre, ophthalmic room, and surgical storeroom. The south wing of the main building, set free by the removal of the out-patient department, has been transformed into an operating theatre with adjoining sterilising and anaesthetic rooms. The theatre is floored with marble terazzo, and a special feature has been made of simplicity of fittings. The autoclave for sterilising dressings is of the latest type, supplied by the Kny Scherer Surgical Company, New York. The old operating theatre at the top of the building has been converted into general accommodation for the staff. The directors have appointed Mr. C. Balfour Paul assistant-surgeon to the Institution.

ETHER-DRINKING IN GLASGOW.—In reply to a petition of the Glasgow Corporation that ether should be included, by an Order of Council, among the scheduled poisons, the Lord President of the Council has replied that, after consulting with experts and the Pharmaceutical Society, he is of opinion that there is no adequate public reason for restricting the sale of ether in Great Britain. He points out that ether is not a poison in the ordinary sense of the word, and if it were to be scheduled because it is an intoxicant there is no logical reason why alcohol should escape similar treatment. The law at present prohibits the sale, under a

penalty of £100, of any derivative of methylated spirit as a beverage, and if any person were caught retailing ether for purposes of consumption as a beverage there would be no difficulty in proving that the ether was made from methylated spirit.

GLASGOW WESTERN INFIRMARY.—The thirteenth annual meeting of contributors was held on the 24th inst., when the report was read. 22,000 outdoor and 6,132 indoor patients were treated during the year, and 94,000 visits made. The maximum number of occupied beds was 475, the minimum 376. The average duration of treatment was 26 days, and the inclusive death-rate just under 8 per cent.

### Special Reports.

#### THE GENERAL MEDICAL COUNCIL.

THE 80th Session of the General Medical Council was opened on the 22nd inst., SIR WILLIAM TURNER, K.C.B., F.R.S., the President, in the Chair.

After the introduction by Dr. MacAlister of Mr. Arthur Thomson, M.A., Professor of Anatomy in the University of Oxford, and by Mr. Young of Professor Alfred George Barrs, M.D., as new members of the Council,

#### PRESIDENTIAL ADDRESS: THE PRESIDENT'S RESIGNATION.

The PRESIDENT, in his opening address, after referring to some recent changes in the *personnel* of the Council, passed on to the business immediately before them. He said that he had communicated to the Clerk of the Privy Council the resolution passed in May last requesting the Lord President to introduce into Parliament a Bill to confer upon the General Medical Council statutory powers to establish and maintain registers of medical and dental students, and to impose a fee not exceeding £1 for registration. Mr. Almeric FitzRoy, in a letter dated November 1st, informed him that communications on the subject had been received from the Presidents of the Royal Colleges of Physicians and Surgeons in London, and he suggested that in the circumstances it might be expedient for the Medical Council to confer with the Colleges with a view to the preparation of a scheme providing for their co-operation towards the desired end, on a basis that would, in some form or other, recognise existing rights. This matter should be considered during the present session. Copies of the judgments in the cases of "O'Duffy v. Jaffe" and "The King (Rowell) v. Registrar of Joint Stock Companies," together with the resolutions of the General Medical Council in the cases, had been forwarded to the Lord President, who had informed the Council, in reply, that his (the President's) letter was referred by him to the Board of Trade for consideration, and he communicated the opinions on the points raised which the Board had received from its legal advisers. After stating that the Council's corporate seal possessed on one side of its central figure the device of a mace, and that that emblem of ceremonial dignity and authority had up to this time been no more than a device on paper, he asked the Council's acceptance of a mace which in its design expressed their identification with the great profession of medicine and their place as the administrative body representative of the three divisions of the United Kingdom. In conclusion, he announced that, although re-elected President of the Council for a further period of five years from December 3rd, 1901, provided he remained a member of the Council, and although his appointment as representative of the University of Edinburgh did not expire until December, 1906, he had formed the opinion, after giving the subject mature consideration, that the time had come when it was advisable that he should retire from the Presidentship of the Council. His duties in Edinburgh as Principal of the University were of an onerous and absorbing nature, and had the first call on his time and energy. Through their favour and confidence, for which he could not too strongly express his grateful acknowledgment, he had occupied the chair during six years. But the business of the

Council was ever on the increase, and with advancing age he felt he should not be able to continue to discharge efficiently the duties of the responsible office to the satisfaction either of himself or his colleagues. He had to request the Council, therefore, to arrange for the appointment of his successor before the end of the present session.

The thanks of the Council were voted to the President for his address on the motion of Dr. MACALISTER, and for the magnificent present of the mace by Dr. PYE-SMITH.

#### ARMY AND NAVY EXAMINATION RETURNS.

SIR PATRICK HERON WATSON moved that the following yearly tables for 1904 be received: Table showing results of competition held on May 16th, 1904, for commissions in the medical staff of the Royal Navy; and table showing results of competition held in July, 1904, for commissions in the Army Medical Service.

Dr. McVAIL seconded the motion, which was agreed to; and the thanks of the Council were voted to the Director-General of the Medical Department of the Royal Navy and the Director-General of the Army Medical Service, respectively, for the returns which they had again furnished.

#### MEDICAL AND DENTAL COMPANIES.

The Council received and entered on the minutes a report from the Executive Committee on the dental business transacted since last session. It was stated in the report that an application from the Dental Board of Victoria for the recognition of its diploma had been received and referred to the Dental Education and Examination Committee for consideration and report during the present session. The answer of the Privy Council to the President's letter, transmitting the Council's resolution respecting companies for the practice of dentistry, and also a Parliamentary return, which had been obtained by Sir John Tuke, in regard to similar medical and dental companies, had been remitted to the Medical Companies Bill Committee for consideration and report to the Council during the present session.

#### MEDICAL "PUPILS" AS ASSISTANTS.

Mr. JACKSON asked the President whether the Council had indicated what meaning was to be attached to the phrase "the proper training and instruction of *bond-fide* medical students as pupils," occurring in the notice regarding the employment of unqualified persons as assistants or otherwise, issued on November 24th, 1897. He said it had come to his knowledge that, in certain districts—in the North of England more especially—there were cases of men who acted as qualified assistants posing as pupils; that was to say, that if any objection were taken to them the reply was that they were pupils. That had been going on for a considerable time. In one instance it appeared that a man employed in a colliery district had been an unqualified assistant under the guise of a pupil for the last thirty-five years.

The PRESIDENT, in reply, read the resolution of the Council embodying the phrase in question, and said that in a case of alleged covering it would rest with the person accused to prove that the assistant employed was, in fact, a *bond-fide* medical student undergoing training and instruction in connection with his fifth year of medical study.

The Council afterwards considered matters *in camera*, and at its rising adjourned for the day.

#### WEDNESDAY, NOVEMBER 23RD.

Much of this day's sitting was devoted to the consideration of penal and disciplinary cases.

#### THE CASE OF MR. C. J. NALLY.

The first case taken was that of Christopher Joseph Nally, registered as of 9 Hardy Terrace, Crook, county Durham, L.R.C.P. & S.I., who had been summoned to appear before the Council in consequence of his conviction at Durham Assizes on July 13th last on an indictment for unlawfully wounding his son, aged 17 months. The accused practitioner, who was sentenced to six months' imprisonment in the second

division, attended in the charge of warders. A petition largely signed by residents in the district in Dr. Nally's favour was also put in. The Council deliberated in private, and when the press were readmitted, the accused practitioner was informed that the Council had decided not to erase his name from the *Medical Register*.

#### THE CASE OF MR. H. S. REVELL.

In the second case, Hugh Stanley Revell, registered as of the Briars, West Hill Road, Southfields, London, S.W., M.R.C.S.Eng. and L.R.C.P.Lond., had been summoned to appear before the Council in consequence of his conviction at the Central Criminal Court on June 20th last on an indictment for obtaining money by false pretences from the guardians of the Wandsworth and Clapham Union. Mr. Revell, upon whom the Recorder passed a sentence which resulted in his release the same day, appeared in person and made a statement, in which he said his defence to the charges would have been that whatever had happened was through inadvertence and stress of work at a time when he was in a most anxious state of mind owing to the illness of his wife. The Council deliberated in private, and when the public were readmitted, the president informed the accused practitioner that the Registrar had been directed to erase his name from the *Medical Register*.

#### PROPOSED REGISTRATION SCHEME.

The remainder of the sitting was mainly occupied with the discussion of a letter from the Privy Council in reply to the proposal of the General Medical Council for the establishment of a register of medical students and the imposition of a registration fee not exceeding £1. Communications on the subject had been received from the Presidents of the Royal Colleges of Physicians and Surgeons, and it was suggested that, in the circumstances, it might be expedient for the Medical Council to confer with the Colleges with a view to the preparation of a scheme providing for their co-operation towards the desired end on a basis that would, in some form or other, recognise existing rights. Sir William Church stated in his letter that, from its incorporation to the present time, under the authority of its charter and statutes the Royal College of Physicians of London had determined the conditions of admission to its professional qualifications, and it claimed to have faithfully exercised the powers entrusted to it for the public good. It appeared to the College that the effect of the proposed measure, so far as it had been made known, would be to transfer to the Medical Council an important part of this power which had hitherto been safeguarded in the Medical Acts, and that it would similarly infringe the authority of the Royal College of Surgeons of England and of the Universities in granting degrees in medicine. It would, moreover, impose an additional pecuniary charge on persons entering the profession, which was believed to be undesirable and unnecessary. The President of the Royal College of Surgeons stated that the passing of such a Bill, without the introduction of restrictions, would probably enable the General Medical Council to lay down conditions of registration, and thus might transfer to that body the right, which that College had exercised for more than a century, of selecting the institutions at which the curriculum of professional study might be commenced by candidates for its diplomas. The council of the College were by no means disposed to relinquish that right. Both Colleges asked to be allowed an opportunity of expressing their views on the subject, as did also the council of the University of Oxford.

Sir CHRISTOPHER NIXON said it would be of no use having a conference with the two Royal Colleges unless they could elicit at the same time the feelings of the other Royal Colleges as to the Bill.

The same opinion was expressed by several other members, Sir ROBERT BALL and Sir JOHN MOORE stating that, in their opinion, the Bill would be opposed by the Royal Colleges in Ireland.

Sir JOHN MOORE moved, and Dr. NORMAN MOORE seconded, a resolution to the effect that a copy of the Council's resolution on the subject be sent to every

licensing body in the United Kingdom with a request that they would favour the Council with their opinion thereon.

Dr. MACKAY moved, and Sir JOHN TUKE, M.P., seconded, an amendment to the effect that, instead of going into conference with the licensing bodies, a detailed statement be prepared of the proposals of the Council with regard to the establishment of a students' register and the institution of a registration fee.

Sir VICTOR HORSLEY said that if anything were to be gained by a conference at all it must be by a farther statement on the part of the Council as to what its position was in regard to medical education, because that, apparently, was wholly misunderstood by many of the licensing bodies. The Privy Council's proposal was made in similar ignorance. The Medical Council itself was the Conference, and that fact did not seem to appeal to the Privy Council in the least, because it had all along proceeded on the lines that the licensing bodies were entitled to as much consideration as the Council. He held that that was fatal to the prospects of medical education. It was time that they made their position clear to the Privy Council.

The debate had not concluded when the Council adjourned.

#### THURSDAY, NOVEMBER 24TH, 1904.

Sir WILLIAM TURNER, president, in the Chair.

Absent, Mr. Morris, Sir Charles Ball, Mr. Tichborne.

The minutes of the last meeting were read, amended, and confirmed.

Moved by Dr. MACALISTER, seconded by Dr. LINDSAY STEVEN, and agreed to: That pursuant to a recommendation of the Executive Committee, Sir Charles Ball be added to the Medical Companies Bill Committee.

The Council then proceeded to the consideration of the case of Herbert Du Cane, registered as of 56 Bolton Road, Darwen, Lancs., Lic. Soc. Apoth. London, 1890, who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor: "That you abused your position as a medical man by committing adultery with a patient, namely, Mrs. Taylor, a married woman whom you had been and were attending professionally."

Mr. J. Rothwell Haslam, solicitor, attended on behalf of the Darwen Medical Society, the complainants; and also represented the husband, Mr. Taylor.

Mr. Ellis J. Griffith, instructed by Messrs. Edwards and Cohen, solicitors, attended to represent Mr. Du Cane.

After Mr. Winterbotham, the Council's solicitor, had read the notice to attend, Mr. Griffith applied for the adjournment of the hearing on the grounds that the notice was not served on Mr. Du Cane till November 7th, he being in Australia, therefore he had not had time to prepare his defence. Mr. Haslam did not oppose the application and left the matter in the Council's hands. The Council deliberated *in camera*, and on strangers being readmitted, the president announced that the application for postponement was acceded to, the case being adjourned to the May meeting, but that the documents of Mr. Du Cane's defence must be given to the Council's solicitor as soon as possible. Mr. Griffith undertook that this decision should be communicated to Mr. Du Cane.

The Council next resumed the case adjourned from May 26th, 1904, of Richard Henry Darwent, registered as of Rokeby Newington, Hull, Yorks, with the triple qualification of Scotland, 1893, who had been summoned to appear before the Council in answer to the following charge, as formulated by the Council's solicitor: "That you abused your position as a medical man by committing adultery with a patient, namely, Mrs. Spink, a married woman whom you had been and were attending professionally, of which adultery you were found guilty by the Decree of the Probate, Divorce, and Admiralty Division (Divorce) of the High Court of Justice, made on October 29th, 1902, in the case of Spink v. Spink, Benson and Darwent, in which you were one of the co-respondents."

Mr. Darwent attended, accompanied by his solicitor.

Mr. F. W. Hill. Mr. M. P. Oldfield, solicitor, appeared on behalf of Mrs. Spink, the complainant, who was not present.

After the president had announced that the members of the Council who were not present at the previous hearing of the case should take no part in the deliberations, the proceedings at the previous consideration of the case were read.

Mr. Hill made a statement in regard to the reason why no steps had been taken to procure the prohibition of the case, for which purpose Mr. Muir (who had appeared for Mr. Darwent in May) had obtained the postponement. This was due to the expense of the proceedings. He then read a letter from Mr. Muir stating that he (Mr. Muir), being detained at the Central Criminal Court, would be unable at this time to resume the defence of his client, and asking for a postponement to a time when he would be able to attend. After Mr. Hill had asked formally for such a postponement, the Council, after having deliberated *in camera*, did not accede to this application. Mr. M. P. Oldfield, at a request from the Chair, read the confession of Mr. Darwent, which had been put in at the trial. Mr. Hill then addressed the Council on behalf of Mr. Darwent, ending with an appeal for justice to be tempered with mercy. After the Council had deliberated *in camera*, the President, on strangers being readmitted, announced the finding of the Council as follows: "Mr. Darwent, the Council has adjudged you guilty of infamous conduct in a professional respect, and has directed the Registrar to erase your name from the *Medical Register*."

At the request of Sir VICTOR HORSLEY, and with the consent of the Council, communications (remitted to the General Council by the Executive Committee) from the Medico-Political Committee of the British Medical Association respecting a letter from the Education Committee of the Borough of Bootle in regard to the giving of a medical certificate by a local chemist and druggist named Procter Williams, in the case of a girl unable to attend school, were considered while the legal advisers of the Council were present.

The Executive Committee on May 24th, 1904, resolved: That the attention of the Medico-Political Committee of the British Medical Association be called to Section 37 of the Medical Act, 1858; that they be informed that on the face of it the certificate forwarded to the Council appears to be invalid under that Section, and that the Council has no jurisdiction over chemists who give invalid certificates. A further letter, however, had been received by the Council from the Medico-Political Committee of the British Medical Association to the effect that it was well aware that the certificate was invalid under Section 37 of the Medical Act, 1858, but that the mere statement of this fact does not appear to the M.-P. Committee to constitute a sufficient recognition of the duties to the public as well as to the medical profession entrusted to the Medical Council; also that the issue of such a certificate by a person not registered as a medical practitioner is an infringement of those privileges of registered medical practitioners which Parliament by the Medical Acts created for the protection of the public, and that it is a fraud upon the public of a kind which the Council may reasonably be expected to use every effort to have punished and thereby prevent its repetition, and that the reply of the Executive Committee appears to the M.-P. Committee of the B.M.A. to indicate a failure to appreciate the true position of the question submitted for the consideration of the B.M.C.

Sir VICTOR HORSLEY said that his object was to obtain the opinion of the legal advisers of the Council as to what could be done in this matter. After some remarks by Drs. Bruce, MacAlister, Windle, Finlay, Lindsay Steven, Caton, and Pye-Smith, Sir John Moore, and Mr. Jackson, chiefly in defence of the answer sent by the Executive Committee, Mr. Muir Mackenzie expressed a desire that he might be permitted to submit his opinion in writing on the following day.

The Council resumed the consideration, adjourned from November 23rd, on the motion of Sir WILLIAM

THOMSON, of the following motion by Sir JOHN MOORE seconded by Dr. NORMAN MOORE: "That a copy of the resolution of May 30th, 1904, be sent formally to every licensing body in the United Kingdom with a request that every such body should favour this Council with their views on the subject, and that the Lord President of the Privy Council should be informed that this Council has placed itself in communication with all the licensing bodies on the subject of a proposed Medical Bill, and will in due course inform the Lord President of the result." together with the following amendment, moved by Dr. MACKAY, seconded by Sir JOHN BATTY TUKE, which, subject to the permission of the Council, has been altered to read as follows: "(1) That the Lord President of the Privy Council be informed that, in the opinion of the Medical Council, it would not be expedient at the present stage to confer with the Royal Colleges on the subject of the resolution of May 30th, 1904; (2) that before proceeding further in the matter, a memorandum be prepared, setting forth the grounds on which the Council is acting in reference to the resolution, and giving the specific proposals which the Council thinks should be embodied in the contemplated Bill." After a discussion, in which Sir Wm. Thomson, Mr. Brown, Mr. Jackson, Dr. Little, Mr. Thomson, Dr. McVail, Dr. MacAlister, Dr. Mackay, and Mr. Tomes took part, the amendment was put and carried by 17 to 5; 8 did not vote, 3 absent.

On the amendment being put as a substantive motion, the following further amendment was moved by Sir CHRISTOPHER NIXON, and seconded by Dr. BRUCE:

"That a reply be sent to the Privy Council stating that this Council now see great difficulties from opposition by certain licensing bodies in asking the Lord President to introduce a Bill giving the General Medical Council statutory power to establish and maintain registers of medical and dental students, and to impose a fee of £1 for registration therein. The General Medical Council will be prepared at the proper time to offer an alternative proposition, which it hopes may be approved by the Lord President."

A discussion followed, in which Sir VICTOR HORSLEY protested against the idea contained in Sir C. NIXON's speech of taxing medical practitioners. Dr. NORMAN MOORE went against the Council trying to extend its power. Mr. BROWN said a few words on registration of students. Sir BATTY TUKE deplored Dr. Norman Moore's remarks in decrying the influence of the Council, as it possesses the confidence of the public and of the profession. Drs. Mackay and McVail and Sir J. Moore made some remarks, and on the amendment being put it was carried 15 to 10; 4 did not vote, 4 absent. The amendment was then put as a substantive motion and carried 14 to 10; 5 did not vote, 4 absent.

Dr. LINDSAY STEVEN then moved, seconded by Dr. MCCALL ANDERSON: "That it be remitted to the Education Committee to consider and report to the next session of the Council whether the adoption by the Council of one or other or both of the following resolutions would not help to secure the attainment of the object the Council had in view in instituting the five years' curriculum, viz.: (1) That the preliminary scientific examination in physics, biology, and chemistry should be passed before the student begins the qualifying study of anatomy and physiology. (2) That before being admitted to the final examination the student should produce evidence that he has devoted the last year of his curriculum exclusively to practical and clinical work and study."

Moved by Dr. NORMAN MOORE, seconded by Dr. MCCALL ANDERSON, and agreed to: "That Clause 1 of Chapter IV. of the Standing Orders be suspended until Dr. Lindsay Steven has finished his speech in support of the motion.

The Council then adjourned.

FRIDAY, NOVEMBER 25TH, 1904.

Absent, Mr. Morris, Mr. Power, Mr. Tichborne.

After the minutes of the last meeting had been read,

the PRESIDENT informed the Council that the Registrar had that morning received a letter from the Pharmaceutical Society of Great Britain in regard to an item in the minutes of the day before. The letter was read. It was to the effect that the person, Mr. Procter Williams, who had given a medical certificate at Bootle was not on the official *Register* of chemists and druggists. The Registrar was directed to append the letter to the Minutes, which were then confirmed.

The Council proceeded to the consideration of the following memorandum prepared by Mr. Muir Mackenzie at the request of the Executive Committee in regard to the question of embodying in the Standing Orders a certain rule of procedure laid down by the Penal Cases Committee for its guidance.

#### MEMORANDUM.

As regards the form and contents of statutory declarations, the following proposed new Standing Order is framed on the basis of the rules which prevail in the Supreme Court, and is adapted from those rules so as to apply to the procedure of the Council in penal cases.

#### PROPOSED NEW STANDING ORDER AS TO STATUTORY DECLARATIONS.

After Clause 9 of Standing Order XIV. insert as a new Clause:—

"Every statutory declaration must state the description and true place of abode of the declarant, and where a fact stated in a declaration is not within the personal knowledge of the declarant the source of the information and grounds for the belief of the declarant in its truth must be accurately and fully stated.

"Declarations and parts of declarations which are made in contravention of this rule will not be accepted as evidence."

It was then moved by Mr. MACALISTER, seconded by Sir VICTOR HORSLEY, and agreed to: "That the new Standing Order be adopted."

The Council next proceeded to the consideration of the subjoined memorandum prepared by Mr. Muir Mackenzie at the request of the Executive Committee in consequence of the following resolution adopted by the General Medical Council on May 31st, 1904.

"That it be remitted to the Executive Committee to consider and draft an instruction to the Penal Cases Committee requiring them to ascertain in each case from the person or persons who have lodged a complaint against a practitioner whether the complainant or complainants have brought under the notice of the practitioner charged their disapproval of his conduct."—(*Minutes*, Vol. XLI., p. 91.)

#### MEMORANDUM.

The cases which come before the Penal Cases Committee for consideration may be shortly divided into two classes—namely, (1) those which are brought before the Committee by private individuals or societies as complainants or informants; and (2) those which are brought before the Committee by public officers or bodies, such as the medical authorities or coroners.

In the latter class of cases there is no person who can be properly called a complainant, and it would be most inexpedient, and indeed impracticable, to require a public body or official, before reporting a case of grave professional misconduct by a practitioner to the Council, to give notice to or communicate with the practitioner.

As regards the former class of cases, namely, those in which professional misconduct by a practitioner is reported to the Council or complained of by a private individual, it would, I fear, cause inconvenience and mischief, and even lead to injustice in some cases, if a general rule applicable to all cases were passed requiring the complainant, before lodging his information and complaint, to give to the practitioner notice of his disapproval of, or his complaint against, the practitioner's conduct. Such a general rule would be inconsistent with the judicial position which the Council occupies in relation to professional misconduct, and is not required for the protection of the party complained of.

If the rule were passed so that the practitioner complained of knew beforehand the subject-matter of complaint, and who the complainant was, he might attempt to arrange and compromise the matter with the complainant before the facts were placed before the Council, or might endeavour to get inconvenient evidence out of the way.

The Council's position is not that of having to decide a dispute between a complainant and respondent, but, when facts are brought to its notice, of having to decide in the interests of the public and the medical profession whether the misconduct alleged and proved against a practitioner requires the erasure of his name from the *Register*. The question whether the complainant disapproves or not of the practitioner's conduct is immaterial.

Under the present practice the complaint or information is considered by the Penal Cases Committee, and that Committee, in its discretion, decides what steps shall be taken, both as regards entertaining the complaint at all and giving notice to the practitioner.

I would suggest, therefore, that no definite instructions to the Penal Cases Committee, applicable to cases generally, should be prepared. I would submit that it may be left to the discretion of the Penal Cases Committee in any case in which in their judgment the complainant should have communicated with the practitioner before lodging the complaint, to require this course to be adopted before proceeding further with the case.

Moved by Sir WILLIAM THOMSON, seconded by Dr. MACALISTER, and agreed to: "That the Council accept the advice given in the memorandum of Mr. Muir Mackenzie and direct the Executive Committee to proceed no further in the matter."

The Council next proceeded to the consideration of the case of Robert Evans, registered as of 74 Brooksby's Walk, Homerton, London, N.E., L.R.C.P. Edin., 1885; M.R.C.S. Eng., 1885, who had been summoned to appear before the Council to answer the following charge, as formulated by the Council's solicitor: "That you have employed as assistant in connection with your professional practice a person not duly qualified or registered under the Medical Acts, namely, Griffith Ellis Williams, and have knowingly allowed such unqualified person to attend and treat patients in respect of matters requiring professional discretion and skill."

Mr. Evans attended, accompanied by Mr. Marpole, his solicitor, and by Dr. John Moore Hall, his partner, as a witness.

Mr. Wynn Westcott, the coroner, who had, as the result of an inquest held by him, brought the matter under the notice of the Council, was not present.

Mr. WINTERBOTHAM read the notice to attend, and in the absence of the complainant read the letter from the coroner to the Registrar and the depositions of various witnesses at the inquest.

Mr. Evans, examined by Mr. Marpole, denied that he had ever given orders to Williams to attend patients, and stated that he never had any suspicion that Williams was treating his patients, and that he had dismissed him at once on learning what had happened. Mr. Evans also answered questions put to him through the Chair and by members of the Council.

Dr. Hall gave evidence in favour of Mr. Evans, and Mr. Marpole then addressed the Council and read several letters from medical men (one from Professor A. Boyce Barrow), all of which spoke most favourably of Mr. Evans.

On strangers being readmitted after the Council had deliberated *in camera*, the President announced the decision of the Council as follows: "Mr. Evans, I am instructed to inform you that the facts alleged against you have not been proved to the satisfaction of the Council, and that your name will therefore remain on the *Register*."

Mr. Muir Mackenzie next read an opinion which he had prepared in answer to the question put by Sir Victor Horsley on the previous day in regard to the giving of medical certificates by unqualified persons: The first sentence of the opinion lays down: "The

effect of Section 37 of the Medical Act, 1858, is to impose a statutory duty and obligation on any public body, what by Statute is required in specified cases to be furnished with a certificate by a medical practitioner, not to accept a certificate by an unregistered person, or such a person as a chemist." However, in Mr. Muir Mackenzie's opinion, the law gives no power to the General Medical Council or to any individual to take proceedings against a public body which failed to carry this out and which accepted certificates from others than medical practitioners.

It was moved by Sir VICTOR HORSLEY, seconded by Dr. MACALISTER, and agreed to: "That this opinion of Mr. Muir Mackenzie be entered on the minutes"; and also: "That a copy of the opinion be transmitted to the B.M.A., as the answer of the Council to their letter."

The Council then proceeded to the consideration, adjourned from November 24th, 1904, of Dr. Lindsay Steven's motion, which was carried.

Moved by Mr. BROWN, seconded by Mr. JACKSON: "That the resolution of May 29th, 1893, be altered so that it reads as follows: That the fifth year be devoted to clinical work at one or more public hospitals or dispensaries, British or foreign, recognised by any of the medical authorities mentioned in Schedule A of the Medical Act, 1858, provided that in the case of students who have served one year's pupillage with a recognised practitioner holding a public appointment or possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities, only six months' clinical work at a public hospital shall be exacted." Comments, mostly unfavourable, on the motion were made by Sir Victor Horsley, Dr. McVail, Sir John Moore, Sir Hugh Beevor, Sir W. Thomson, Drs. MacAlister and McCall Anderson, and the motion was lost, 24—3; 1 did not vote, 5 absent.

In answer to a question by Dr. Finlay, the PRESIDENT stated that the University of London had been visited by Sir John Batty Tuke, accompanied by the Inspector, in the present month, but that the Report would not be ready for consideration till next Session. The University of Oxford would not hold an examination till December, when it would be visited by Dr. McCall Anderson, accompanied by the Inspector. He explained that as the two Universities had been revising their regulations it was not possible to inspect the new examinations at an earlier date.

Moved by Dr. BRUCE, seconded by Mr. JACKSON, and agreed to: "That the Report by the Public Health Committee be received and entered on the minutes."

Moved by Dr. BRUCE, seconded by Mr. JACKSON, and agreed to: "That the recommendation in the second paragraph of the Report of the Public Health Committee be adopted, *viz.*, that the regulations for the Diplomas in Public Health of the University of Liverpool and of the University of Leeds be approved."

Moved by Dr. BRUCE and seconded by Mr. JACKSON: "That the recommendation contained in the last paragraph of the Report of the Public Health Committee be adopted, *viz.*, that the Council should refuse a certain application for exemption." After a discussion, in which Drs. MacAlister, Lindsay Steven, Norman Moore, Sir Chas. Ball, Dr. McVail, and Sir J. Batty Tuke took part (most of these members of the Council being against the exemption in question being granted), it was moved by Sir JOHN BATTY TUKE, seconded by Dr. McVAIL, and agreed to: "That this debate be now adjourned till Monday, November 28th, 1904."

The Council then adjourned.

#### CENTRAL MIDWIVES BOARD.

MEETING OF THE CENTRAL MIDWIVES BOARD HELD  
NOVEMBER 24TH, 1904.

DR. F. H. CHAMPNEYS in the Chair.

A LETTER was read from the hon. secretary of the Metropolitan Counties Branch of the British Medical Association, asking for the co-operation of the Board with the London County Council in obtaining powers

from Parliament to pay registered medical practitioners, when called in by midwives, in emergencies. After consideration it was decided "that the Board would give assistance in the matter, but that the suggestion must come from the British Medical Association." A letter was also read from the Clerk of the Monmouthshire County Council, asking the Board's construction of the words "otherwise than under the direction of a qualified medical practitioner." (Midwives Act, Section 1, sub-section 2.) A medical man may leave an uncertified midwife in sole charge of a case; is she then acting under his directions? After discussion Dr. CULLINGWORTH proposed that "The Central Midwives Board cannot give a general answer, the point being a legal one on which no authority has yet been given us."

Miss WILSON then moved: "That trained women inspectors be appointed by the Board to inspect institutions applying for recognition to the Board." Sir William Sinclair objected to the word "women," and it was finally decided to omit the word, and the resolution was passed.

Dr. CULLINGWORTH moved: "That the representatives of the press be required to withdraw during consideration of matters having reference to the judicial or penal powers of the Board, or of applications for recognition or approval." It was resolved "That the motion be postponed till the procedure of the General Medical Council be inquired into."

The meeting shortly afterwards adjourned.

TAORMI. A MINERAL SPRINGS AND SYRACUSE.  
*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—I have read your notes on various health resorts of Great Britain and the Continent with much interest, and having recently visited Syracuse, I shall be glad if you will allow me to state for the information of those of your readers who contemplate journeying in that direction that I found the town not only traditional as to antiquities, but amazing in its grand works of architecture, carried out by our ancestors, who were supposed to be at that epoch the conquerors of the world. We may have modified or embellished art, but we must admit, when visiting spots like this, that we are only copying on different lines what our forefathers have accomplished. Speaking from the point of view of a physician, I believe that the climate of Syracuse would suit persons suffering from hepatic disorders or chest diseases. The atmosphere is dry and bracing, rain is not infrequent, and the barometer temperate. To those who desire to visit the Taormina mineral springs in search of health and fresh surroundings, the best route is undoubtedly *via* Syracuse, and at the Grand Hotel of that city invalids and convalescents receive all care and attention; whilst visitors who are not invalids will do well to go there, not only for the accommodation afforded, but for the panoramic view obtainable therefrom, for its cleanliness and for its hygienic conditions generally, which are so unusual in these parts.

I am, Sir, yours truly,

CHARLES HELFIELD, M.A., M.B., L.M.

Malta, Nov. 23rd, 1904.

#### CONSTIPATION.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Dr. Tom Robinson has hardly done himself full justice in his too brief paper he contributes to your issue of this week; but he has at least furnished a text for a discussion which might with advantage be taken up by your readers. The enormous sale of quack remedies for constipation, not to speak of aperient mineral waters, affords unmistakable evidence of the widespread prevalence of the complaint in question. It is no doubt in the vast majority of cases a merely functional derangement due to faulty personal

management and is in most cases to be cured by proper dietary, and wise personal hygiene. The suffering which accompanies the condition of sluggish bowels is very real; and in most cases patients have sufficient intelligence to trace to it the mental depression which is often its most painful symptom. No doubt it is possible to classify cases broadly, but no malady needs more careful discrimination in every instance; in none is routine treatment more certain to end as a rule in failure. On the other hand, the cases are very rare which cannot be made amenable to treatment after thorough investigation and patient experiment in dietary, habits, and administration of drugs. The habitual taking of purgatives everyone may agree with Dr. Robinson in condemning; but we must distinguish between drastic purgatives and true laxatives. Of these latter we have now a good choice; and many of them may be used habitually without ill-effect. Constipation is one of those minor ailments which the general practitioner too often neglects. In many cases he prescribes aperients without sufficient investigation, and drives the patient to seek relief from quack nostrums. With intelligent patients it will always, in the best sense of the word, pay to explain matters at full length, to assure them that permanent relief can be had if proper time and patience be bestowed on observation and experiment with both diet and drugs. This is the course which is so often overlooked by the general practitioner in dealing with other or all so-called minor ailments, and it is a course which as often loses for him the confidence of at least that class of patient—perhaps not the largest class nowadays—who have confidence in medical science and due respect for its votaries.

I am, Sir, yours truly,

G. P.

November 24th, 1904.

### Obituary.

#### DR. G. VIVIAN POORE.

DR. POORE, whose death, at the age of sixty-one, is announced, was born at Andover, and was educated at the Royal Naval School, New Cross, and at the Medical School of University College Hospital, London, taking his M.R.C.S. in 1866, and the M.D. Lond. degree in 1871, and in 1877 he was elected a Fellow of the Royal College of Physicians, London. His first professional appointment was that of surgeon on the Great Eastern steamship, while engaged in laying the Atlantic cable, and he was afterwards medical attendant to the late Duke of Albany, and in 1872 to the King (as Prince of Wales.) He also filled at various times the office of Professor of Medicine and Clinical Medicine at University College, physician to University College Hospital, consulting physician to the Royal Hospital for Children and Women, and to the Cheyne Hospital for Children at Chelsea. Dr. Poore received the decoration of Knight Commander of the Dannebrog for professional services to Princess Thyra, Duchess of Cumberland, in 1872. In 1891 he was secretary-general of the Sanitary Congress. Dr. Poore had written largely on sanitation and cognate questions, and had published a number of medical works.

#### MAJOR THOMSON, OF PENRITH, M.D., [EDIN.

DR. D. G. P. THOMSON, of Bishopsyards, Penrith, died at Algiers after a very brief illness. He was ordered to winter abroad owing to lung trouble, and only left home with Mrs. Thomson three weeks ago. Meningitis following influenza is understood to have been the cause of death. In his younger days he was an enthusiastic football player, and several times captained the Cumberland team. He was an ardent volunteer, and three years ago was promoted to the rank of Major, after commanding the two Penrith companies for several years. Dr. Thomson was also medical officer of health for Penrith, besides holding other public offices.

## Medical News.

### Irish Medical Schools and Graduates' Dinner.

THE annual dinner of this popular Association was held last week in London at the Hotel Cecil, the president, Surgeon-General C. Sibthorpe, C.B., presiding, supported by a large and distinguished company, amongst whom were many ladies. The dinner was served in the Grand Hall, and was in every way worthy the reputation of the establishment, but climatic conditions were at their worst on that particular evening, and many empty chairs were seen in consequence. Albeit everything went off with considerable *eclat*, and a thoroughly enjoyable *reunion* resulted. After the usual loyal and patriotic toasts had been duly honoured, Professor E. Halloran Bennett proposed (on behalf of Sir John W. Moore) the toast of "Our Defenders," which was responded to by Surgeon-General A. M. Branfoot and Surgeon-Lieutenant F. Swinford Edwards, the former representing the Navy and the latter the Volunteers. The toast of "Our Guests" was proposed by Surgeon-General C. B. Mosse, C. B., C.M.G., and responded to by Professor Bury and Dr. William Hill. In proposing the toast of "Ourselves," Dr. Pye-Smith, Vice-Chancellor of the University of London, said that he had the honour of proposing the toast of the medical profession of Ireland, which he regarded as the most distinguished in the world, and he regarded it as a high honour that he had been brought into contact with some of the biggest and brightest names on the Irish Medical Register. He regretted he was not an Irishman, and he could only say it was no fault of his. However, he took comfort in the fact that he had taken measures that some of his descendants would be able to compete with the native wit of the sister isle. The president replied in very felicitous terms, and proposed, as the final toast of the evening, the "Health of the Hon. Sec. Mr. Swanton," who, he said, as secretary to the committee, had worked wonders in promoting the success of the Association.

### The Hæmatogen Case.

CONSIDERABLE medical interest was aroused in this case, which was tried in June last before Mr. Justice Warrington and a jury. The action was then brought by Dr. Hommel, a Swiss physician, trading in this country as Nicolay and Co., to restrain the defendants, a Messrs. Gebruder, Bauer and Co., of Mincing Lane, London, from infringing the plaintiff's registered trade-mark, "Hæmatogen," and from passing off goods not of the plaintiff's make as and for the plaintiff's goods. The plaintiff made a preparation of hæmoglobin, which he put upon the market under the name of "Hæmatogen," and registered it as his trade-mark. The plaintiff's case was that no other preparation had been sold under the name of "Hæmatogen" in the United Kingdom up to 1902, and that anyone who asked for, or ordered, or prescribed Hæmatogen intended to refer to the plaintiff's preparation and no other. The plaintiff alleged that the defendants, who acted as the London representatives of a Hamburg firm, had recently been soliciting orders for, and selling in London, a preparation not manufactured by the plaintiff under the plaintiff's trade mark "Hæmatogen," and had been supplying his preparation in response to orders for Hæmatogen to the damage and injury of the plaintiff. The defendants, on their part, contended that Hæmatogen was not invented by the plaintiff or first used by him, but that the word was in common use in Germany and elsewhere, and that preparations so called were previously well known to medical men, chemists and scientists. The plaintiff and the defendant and a great many medical men, chemists and scientists were examined, and many dictionaries and medical text-books, both English and foreign, were put in evidence as to the origin and meaning of the word "Hæmatogen," and to show that it had not been invented by the plaintiff, but was the recognised description of an organic form of iron, or of a preparation tending to form blood.

The learned Judge held that the word "Hæmatogen" must be struck off the Register of Trade Marks on the ground that it was not an "invented word." He also held that the plaintiff had failed to show that the word had come to mean his preparation exclusively, and that the defendants had not been guilty of passing off their goods as those of the plaintiff. The action was accordingly dismissed with costs.

Lord Justice Vaughan Williams delivered judgment on Friday last, November 23rd, in the Supreme Court of Judicature; he said that he agreed with the conclusion of Mr. Justice Warrington that it had not been proved that the word "Hæmatogen" had acquired a secondary meaning as denoting only the plaintiff's preparation. His lordship did not doubt that among doctors and chemists the word had a meaning independent of its primary meaning. The Court had to consider whether among the persons who had to deal with this kind of preparation the word would mean the plaintiff's preparation exclusively, but his lordship agreed with Mr. Justice Warrington that on the evidence it was not proved that the word had acquired a secondary meaning which attached it to the plaintiff's preparation only. The appeal must therefore be dismissed with costs. Lord Justice Romer also agreed in the conclusion of Mr. Justice Warrington, and adopted his reasoning. Lord Justice Cozens-Hardy agreed, and adopted every word of Mr. Justice Warrington's judgment.

#### Charing Cross Hospital.

At the annual distribution of prizes on Wednesday last to the students attached to this hospital, the following were the chief awards for the winter session, 1903-4, and the summer session, 1904:—Epsom Scholar, Mr. N. G. Salmon; Livingstone Scholar, Mr. R. H. H. Jolly; University Scholar, Mr. W. D. Keyworth; Llewellyn Prize, certificate, and £25, Mr. J. W. Evans and Mr. R. K. Shepherd (equal); Golding Prize, certificate, and £10, Mr. R. H. H. Jolly; Pereira Prize, certificate, and £5, Mr. H. H. R. Bayley; Governors' Clinical Gold Medal, Mr. J. W. Evans; Huxley Medal, with prize of £10, Mr. W. S. Fenwick; anatomy (senior) prize, Mr. W. S. Fenwick; anatomy (junior) prize (Steadman), Mr. R. H. H. Jolly; prize (school), Mr. W. E. Wilks; biology, Mr. P. E. Stibbe; chemistry, Mr. P. E. Stibbe; physiology (senior), Mr. W. S. Fenwick; physiology (junior), Mr. R. H. H. Jolly; medicine (senior), Mr. J. W. Evans; medicine (junior), Mr. W. W. D. Chilcott; surgery (senior), Mr. R. K. Shepherd; surgery (junior), Mr. W. W. D. Chilcott; practical medicine, Mr. L. E. M. Smith; psychological medicine; Mr. J. W. Evans; ophthalmology, Mr. R. K. Shepherd; practical midwifery, Mr. E. C. Sprawson; practical chemistry, Mr. C. J. Butler; midwifery, Mr. W. K. Beaman; pathology, Mr. W. K. Beaman; public health, Mr. R. K. Shepherd; therapeutics, Mr. J. W. Heekes; forensic medicine and toxicology, Mr. W. K. Beaman; materia medica, Mr. T. W. R. Strode.

#### The Medico Legal Society.

A MEETING held on November 8th, Sir Wm. Collins, the President, being in the chair. He paid a memorial tribute to Mr. C. H. Hopwood, K.C. (a late vice-president) and hoped that the Society would see its way to appoint a standing committee to watch medico-legal progress. Dr. Clay Shaw read a paper on "An Obscure Form of Alcoholism Involving Irresponsibility," which we hope to publish in our next. Miss Louise Appel, M.B., narrated the Hindu (subjective) method of viewing responsibility. Mr. J. Troutbeck thought a physical examination of many prisoners was desirable prior to their conviction. Dr. Lewis Lewis agreed; he had known epileptics commit criminal acts after being "cured." Dr. F. S. Toogood, from his experience at Lewisham Infirmary, stated that two-thirds of the lunatics received there became sane after a few days' residence. The President thought lawyers held a statical, medical men a dynamical, view of responsibility. Delirium tremens was not, in his clinical

experience, precipitated by sudden abstention from alcohol. Dr. Stanley B. Atkinson then considered "Definitions of Accident and Accidental," as used in the coroners' court, insurance policies and Workmen's Compensation Acts. Dr. A. D. Cowburn cited cases of nervous shock and held such often led to organic derangements. Several others joined in the discussion which was concluded by the President who suggested the possible wide extensions of recent legal decisions which had confused insurance companies as to the exact nature of an accident.

#### Royal College of Surgeons of England.

THE Bradshaw Lecture will be delivered in the Theatre of the College by Professor A. W. Mayo Robson, F.R.C.S., Vice-President, on Thursday next, December 1st, at 5 o'clock p.m. precisely. The subject of the Lecture will be "Cancer and its Treatment." Fellows and Members of the College are invited to attend. Students and others who are not Fellows or Members of the college will be admitted on presentation of their private visiting card.

#### National Dental Hospital.

THE Students' Annual Dinner of the National Dental Hospital was held at the Trocadero Restaurant, London on November 19th. The chair was taken by Mr. Andrew Clark, who remarked that the President of the hospital was the Prince of Wales. In proposing the toast of "The National Dental Hospital and College," the Chairman explained how the hospital could lay claim to the title of "National," and proceeded to show that the dentist of the present time cannot be a mere mechanic, but must receive instruction in general medicine and surgery before receiving a necessary qualification to practice.—Professor A. S. Underwood, of King's College, proposed the toast of "The Past and Present Students," which was responded to by Mr. Rose and Mr. Cooke. Mr. Harry Rose submitted the toast of "The Visitors," which was acknowledged by Professor Spencer. Mr. Goadby proposed "The Health of the Chairman," and the proceedings terminated.

#### Trinity College, Dublin.

THE following have passed, during Michaelmas term, the Final Examination in Medicine—Section B: Robert A. Askins, Henry H. A. Emerson, equal; George E. Nesbitt, John W. Burns, Francis J. Usher, Charles E. C. Williams, William G. Harnett, Henry H. White, James M. Harold, John Murdoch, and Hercules J. Knox.

#### Navy Medical Service.

THE following appointments have been officially gazetted:—

*Fleet Surgeons.*—H. J. Hadden, M.B., B.A., to the "President," additional for three months' hospital course, to date November 16th; H. Elliott, M.B., to the "Empress of India"; J. M. Rogers, to the "Lion," to date November 14th.

*Staff Surgeon.*—E. A. Penfold, M.B., to the "Britannia," additional, for the "Highflyer," on commissioning, to date November 18th.

*Surgeons.*—R. Thompson, to the "Britannia," additional, for the "Highflyer," to date November 18th; M. Cameron, H. C. Whiteside, to the "President," additional, for three months' hospital course; and J. H. Lightfoot, to the "Albacore," to date November 14th.

It is announced in connection with the visit of the King and Queen of Portugal to this country, Don Antonio Maria de Lancastre, physician to their Majesties, has been appointed an Honorary Knight Commander of the Royal Victorian Order.

DR. E. BOYS RUSSELL, of Lismore, has been appointed to the Commission of the Peace for the county of Waterford.

THE first annual dinner of the United Hospitals Clinical School, University of Liverpool, will take place at the Adelphi Hotel, Liverpool, on Saturday, December 3rd, at 7.15 p.m.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office, these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**QUESTIONS.**—The article on the "Sea Air Cure" contained in M.P. & C. for August 3, was virtually a synopsis of the Transactions of the Nice Congress and was derived in great measure from the excellent resume thereof published in the "Bulletin Medical d'Algerie" for 1904, fol. 327 by Dr. Bordet, of Algiers, to which we must refer you for further details.

Dr. McWALTER'S letter is unavoidably crowded out of our present issue.

### CELLULOID COMBS.

**WEST TOWN (Somerset).**—A correspondent calls attention to the danger of celluloid combs for the hair sold as tortoiseshell and encloses account of a case in which combs of the kind caught fire and inflicted serious injury to a lady's head. We thank our correspondent for calling attention to the matter, which will be found alluded to more fully in our editorial columns.

**BEEBEEBEE.**—This affection is primarily a degeneration of motor nerve-endings. The disturbing factor is apparently connected with bad food, although its precise nature has not been hitherto determined.

**A SALOP PRACTITIONER.**—The first obvious step is to make an examination of the blood. Should you not have the necessary time and skill at command send to one of the research laboratories.

### THEY LIKE THEIR MEDICINE STRONG.

Overheard in a hospital waiting room. "What was I-a-mayin' ? Oh! The medicine, its only 'art water. I looked through the pidgin-ole where they serves it out, one day, and I see the dispenser, meself, a-fillin' up the bottle out o' the water tap, and I went strite to the doctor, I did, and I see. 'Was that the way pore people orber be treated? . . . What did 'e say? . . . Only larfed, and said, 'Better complain to the Inland Revenue'; I dunno wot 'e meant." —"Our Hospitals and Charities Illustrated."

**WINSTANLEY (Beds.).**—You will find the answer to your question in the following quotation from Churchill's "Medical Directory." "In all cases where a servant falls ill or meets with an accident, and is unable to pay for necessary medical assistance, the parish is bound to supply assistance, although the servant may not have previously stood in need of parish relief. If a deputy overseer or even a mere stranger, direct a surgeon to attend a poor man, such person is liable for the surgeon's bill. A medical man called on by the police to visit a sick person in a station-house within the metropolitan district may claim the sum of 3s. 6d. for every such visit in the daytime, and the sum of 7s. 6d. for every such visit paid between the hours of 11 p.m. and 8 a.m."

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY NOVEMBER 30th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. J. Smith: Clinique. (Surgical.) 5.15 p.m. Mr. G. B. M. White: Whitlow and Suppurations in the Hand.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—5 p.m. Demonstration.—Dr. Dundas Grant: Larynx.

### THURSDAY, DECEMBER 1st.

**ROYAL SOCIETY** (20 Hanover Square).—8.15 p.m. Paper: Dr. W. Cotton, of Bristol, on "The Perspective Nature of X-Ray Projection." Short note by J. H. Gardiner, Esq., F.O.S. The New Ultra-violet Glass recently produced by Messrs. Schott and Gerrosen, of Jena. Both will be illustrated by the Epiliascope.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND**—5 p.m. Mr. A. W. Mayo-Robson: Cancer and its Treatment. (Bradshaw Lecture.)

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. H. Tilley: Earache, its Causes, Diagnosis, and Treatment.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture: Dr. T. Lister: Congestion of the Lungs. (Post-Graduate Course.)

### FRIDAY, DECEMBER 2nd.

**WEST KENT MEDICO-CHIRURGICAL SOCIETY** (Royal Kent Dispensary Greenwich Road, S.E.).—8.45 p.m. Mr. J. Bland-Sutton: Abdominal

Pregnancy in Women, Cats, Dogs, and Rabbits. Conventions. Exhibits:—The President: Slides in the Oxyhydrogen Lantern.—Dr. S. Barnett: Stereoscopic Skiagrapha.—Mr. J. J. Vesey: (1) Apparatus for Wireless Telegraphy (in action); (2) Some Fluorescent Materials shown in Ultra-violet Light by means of the Optical Lantern; (3) Radium and Polonium.—Medical Supply Association: Surgical Instruments.—Messrs. Duncan, Flockhart, and Co.: Therapeutic Preparations.—The Galen Manufacturing Co.: Surgical Dressings.

**WEST LONDON MEDICO-CHIRURGICAL SOCIETY** (West London Hospital, Hammersmith, W.).—8.30 p.m. Papers.—Dr. A. E. Russell: The Diagnosis of Acute Abdominal Disease.—Dr. C. R. Fennell: Juvenile General Paralysis.

**SOCIETY OF ANESTHETISTS** (20 Hanover Square, W.).—8.30 p.m. Resumed Discussion on the Vernon-Harcourt Inhaler. Dr. B. Buxton, Sir Victor Horsley, Mr. Silk, Mr. Low, Mr. MacHardie, Mr. H. Hilliard, Mr. Bakewell, and Mr. Crouch will take part.

**LARYNGOLOGICAL SOCIETY OF LONDON** (29 Hanover Square, W.).—5 p.m. Cases, Specimens, &c., will be shown by Dr. Law, Sir F. Semon, Dr. Bronner, and others.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. S. Stephenson: Clinique. (Eye.)

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital).—4.30 p.m. Lecture: Dr. Whiting: Modern Methods in the Diagnosis of Stomach Disorders.

## Vacancies.

The Hospital for Sick Children, Great Ormond Street, London, W.C.—Resident Medical Superintendent. Salary £100 per annum, with board and residence in the hospital and £5 weekly allowance. Applications to the Secretary.

Addebrooke's Hospital, Cambridge.—Secretary-Superintendent. Salary £250 per annum. Applications to the Secretary, 2 St. Andrew's Street, Cambridge.

Jersey General Dispensary and Infirmary.—Resident Medical Officer. Salary £150 per annum, with rooms, gas and attendance. Applications to Hon. Secretary, Infirmary, Jersey.

Royal Hospital for Incurables, Dublin.—Resident Medical Officer. Salary £180 per annum, with board &c. Applications to J. I. Thompson, Registrar.

Stirling District Asylum, Larbert, N.B.—Assistant Medical Officer. Salary £150, per annum, with board, &c. Applications to the Medical Superintendent.

Liverpool Dispensaries.—Assistant Surgeon. Salary £100 per annum, with board and apartments. Applications to Sam B. Leicester, Secretary, 56 Vaughan Road, Liverpool.

London Hospital, Whitechapel, E.—Medical Registrars. Salary £100 per annum. Applications to E. W. Morris, Secretary.

Holloway Sanatorium Hospital for the Insane, Virginia Water, Surrey.—Junior Assistant Medical Officer (Lady). Salary £150 per annum, with board, lodging, washing, and attendance, &c. Applications to Dr. W. D. Moore, Medical Superintendent.

Dr. Stevens' Hospital.—House Surgeon. Salary £100 per annum, with apartments, fire and light. Also a Pathologist. Applications to the Secretary. (See Advt.)

## Appointments.

JOYNS, FRANCIS JAMES, M.R.C.S., L.S.A., Medical Officer of Health for the Dursley (Gloucester) Rural District Council.

ODEN, ODENE WATSON, M.D., B.S. Durh., M.R.C.S. Eng., L.R.C.P. Lond., Honorary Physician to the Hospital for Sick Children, Newcastle-upon-Tyne.

SAUNDERS, G. J. M.B., B.S. Aberd., Certifying Surgeon under the Factory Act for the Burghhead District of the county of Elgin.

STYMS-THOMPSON, H. E. M.A., M.B. Cantab., M.R.C.P. Lond., has been appointed an Assistant Physician to the Royal Hospital for Diseases of the Chest, City Road, E.C.

SAVILL, MRS. AGNES F. M.A., M.D., M.R.C.P.I., has been appointed an Hon. Assistant Physician to St. John's Hospital for Diseases of the Skin, Leicester Square, London.

TOVEY, ARTHUR, M.R.C.S., L.R.C.P., has been appointed a Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square, London.

## Births.

MURPHY.—On Nov. 23rd, at Portobello House, Dublin, the wife of W. Murphy, L.R.C.S. and P.I., Coolgreany, co. Wexford, of a daughter.

## Marriages.

CODD—COOPER.—On Nov. 23rd, at the Parish Church, Bromley, Kent, Arthur Frederick Gamble Codd, M.B., F.R.C.S., of Holwood Lodge, Bromley, Kent, son of the late Arthur Gamble Codd, of the Inner Temple, to Ada Margaret, second daughter of Mr. and Mrs. George Quilton Cooper, of Willow Bank, Bromley.

## Deaths.

FOOTE.—On Nov. 23rd, at Portland House, Andover, George Thos Poore, M.D., F.R.C.P., youngest son of the late Commander John Poore, R.N., aged 61 years.

## Presidential Address

ON

### THE DOSAGE OF REMEDIES. (a)

By J. THEODORE CASH, M.D., F.R.S.,

Regius Professor of Materia Medica in the University of Aberdeen

WE find chronicled an astonishing liberality in the prescription of remedies by the ancient physicians. An instructive paper published in Edinburgh by Dr. Milligan some eighty years ago gives much interesting information on this point. The wise and cautious Dioscorides ordered 62 grains of aloes as a medium purging dose, or in its place elaterium  $10\frac{1}{2}$  grains or scammony 30 grains. The antidote of Mithridatus had its 35 constituents of which opium formed the forty-third part by weight, so that calculating from the amount given, no less than 6 grains of opium would go to an anodyne dose. Marcellus ordered 31 grains of aloes as a laxative, Rufus Ephesius drachm doses of pulp of colocynth. Hippocrates ordered an obolus containing 10.5 grains of elaterium. No doubt is admissible as to the amount prescribed, as the value of the denarius, the weight quoted, is known.

Are these large doses satisfactorily accounted for on the hypothesis of Arbuthnot that the prescriptions were written in multiples (probably of 4 as suggested by Duncan) of the amounts actually intended to be administered, with the object of concealing the method of treatment, or may it have been that drugs were frequently so inert owing to imperfect methods of preparation and the presence of adulterations that such large doses were actually required to produce a desired effect? It appears to be unlikely that the ancients had any peculiar tolerance towards remedies, their physique was inferior to that of the Gauls, and though rickets, struma, and chronic rheumatism seem to have been rare among them, their excesses both in eating and drinking would predispose to disorders which would in various ways lessen their resistance.

Our knowledge of the existence, development, and separation of the active principles of plants is of comparatively recent growth, the necessity for a standardisation of many preparations has been recognised, and a further extension in this direction is desirable in the interests of exact medication.

As concerning our present system of dosage an advance has been made in the latest edition of the British Pharmacopœia by the specification for many preparations of a dosage applicable to repeated administration as well as for a single dose. The question, What is meant by repeated adminis-

tration? may not admit of an easy answer in every case. Some remedies may be repeated with advantage every two or three hours, others not oftener than every five or six hours. The speed of absorption and elimination or de-energisation must be considered carefully in this connection. On the whole the quotations of a summated dosage for a period of time such as twelve or twenty-four hours is likely to be of more use to the prescriber who desires to know what amount of his remedy may be safely but effectively given. To him should be left the distribution of the fractional doses he may elect to use, and the time of their administration.

The German Artznerbuch acknowledges this principle by quoting a "day's dose" for some of the more important drugs and preparations contained in its pages. If we examine the relationship of the day's dose to the single dose, we find that whilst in the majority of cases the summated dose is thrice the amount of the single dose, there are many exceptions to this relationship—thus, for example, whilst extract of opium has for the day's dose three times the amount of the single dose, the nitrate of strychnine has only twice as much, whilst the sodium salicylate of theobromine has six times the amount.

The dynamical properties of individual remedies, and the probable duration of their operation within the tissues, are to be considered in connection with the therapeutical purpose for which they are given. It is quite clear that a uniform system cannot be applicable to all the remedies we employ, and that the stereotyped formula "take three times a day" may often be amended with much advantage to treatment.

In order to illustrate the variation in effect producible by repeated dosage, two series of experiments were illustrated diagrammatically. The standard chosen was the fall of temperature produced by two alkaloids (A and B) nearly related to one another botanically and chemically. The plan adopted was the following:—After ascertaining the exact lethal proportion of each per kilo body weight for rabbits, a calculated fractional dose was given hypodermically at regular time intervals. The fraction of the lethal varied from  $\frac{1}{8}$  to  $\frac{1}{2}$ , and the time of re-administration from 45 minutes to 4 hours. It was found that in the case of the slightly less toxic body, the elimination or de-energisation occurred more rapidly than in the case of the slightly more toxic alkaloid.

With the former, doses of  $\frac{1}{8}$  to  $\frac{1}{4}$  of the lethal may be followed by a slight summation in effect when re-administration is made every 45' or 60', but if re-administration is at intervals of, or greater than, 90' the initial effect is neither maintained nor reproduced in extent. Even after

(a) Delivered before the Aberdeen Medical-Chirurgical Society, November, 1904.

a proportion of  $\frac{1}{4}$  lethal, there is only slight indication of summation when an interval of 90' is allowed to elapse before re-administration. Should the proportion of the dose be so large as  $\frac{1}{2}$  of the lethal, a progressive fall of temperature is observed when re-administrations occur every 45', and a fourth dose proves fatal; but if the interval is extended to 60', the same proportionate amount may be given a fourth or even a fifth time, and although a distinct summation of effect is registered, the total fall of temperature is less than that following three administrations at intervals of 45'.

These and other observations made with the body A were contrasted with those in which B was employed. As this body is eliminated or otherwise de-energised more slowly than A, greater evidence of summation is observable after doses bearing a small proportion to the lethal, re-administered at short time intervals as well as of larger proportions re-administered at longer time intervals.

It is probable that the greatest therapeutical advantage would not be derived from an identical method of employing these two bodies A and B in practice, given a permissible dose for a certain time period: the size of the fraction, as well as its allocation in point of time, would differ.

Such a conception which recognises an individuality in a remedy is no mere fancy; it is worthy of study as bearing directly upon the most efficient handling of that remedy as a therapeutical weapon.

In connection with the prescribing and preparation of remedies, an early and general adoption of the decimal system of weights and measures is highly desirable. In medicine, as in commerce, our present chaotic system is a bar to a mutual understanding with other countries, whilst it is a constant difficulty to ourselves. Our Continental neighbours, with the exception of Russia, have adopted the more workable and intelligible system, and there is no probability that they will ever relinquish it.

Our present system as applied to medicine is not merely antiquated, but intrinsically bad; as applied to commerce, its operation is well summed up by Lord Lansdowne when he describes it as "distracting to learners, obstructive to trade, and probably advantageous to no one."

There must necessarily be a period of calculation and study for those of us who are accustomed to the older system, before the gramme and the cubic centimetre become usable actualities, but the period need be but a brief one. Sir Wm. Ramsay assures us that the change to the employment of the decimal system was effected in Germany without any trouble in a week's time, and the Scandinavian countries adopted it with equal ease and celerity. I trust that our next Pharmacopœia will give doses in terms of the decimal system and thus render the transition more easy, both to practitioners and students of medicine. One other question affecting dosage is of serious importance.

When the decimal system is adopted and prescribers make daily use of it, by what method shall the patient have his dose measured? To direct that he shall take so many cubic centimetres of the contents of his bottle would probably give rise to much trouble and dangerous misunderstanding, for the system in nine cases out of ten would be foreign to him. To regulate the

dosage by the so-called "domestic measures"—spoons and wineglasses—would be a serious error, for the capacity of these individually varies enormously, so that their use is in most cases utterly fallacious. (Parenthetically, it may be stated that the capacity of the tea-spoon may be anything from 40 to 90 M, so that the patient may receive only two-thirds of his dose, or, on the other hand, half as much again according to the resources of his table equipment.)

The larger measures are even less trustworthy. Now the use of these should be altogether abandoned, and a glass measure—accurate, but of small cost—should be universally employed.

Such a measure might suitably have an eprovette from the cylinder having a height of about 20 cm., with a diameter of 2 cm. On this for graduation marks might be placed, indicating (from the lowermost upwards) capacities of 2.5, 5, 10 and 20 c.c. respectively.

The first might be indicated by the numeral I, the second II, the third IV, as it represents (2.5 c.c. x 4); the uppermost 8 (2.5 x 8). The patient might recognise these as so many parts, so that when the physician directed 4 parts at certain time intervals he would measure or have measured for him his 10 c.c., without risk of confusion.

It seems likely that some such method would materially assist the prescriber reforming his system, and if some recollection of the old nomenclature serves in any way to steady him in finding certain parallels with the newer standard, he could associate the figure 1 (2.5 c.c.) with a small teaspoonful; 4 (10 c.c.) with a large dessert-spoonful; and so on.

By the patient, who would receive an exact measure for 3d. or 4d., the outlay could only be regarded as a good and safe investment, whilst the progress of therapeutic observation would be cleared of many fallacies, which are apt to arise when an æsthetical silver teaspoon takes the place of its ample brittanic metal predecessor as the trusted domestic measure of the family.

## PAROTITIS AS A COMPLICATION OF GASTRIC ULCER.

By W. SOLTAU FENWICK, M.D., M.R.C.P.  
Physician to the Evelina Hospital for Sick Children and to the  
London Temperance Hospital;

AND

HERBERT RHODES, M.B.Lond.,  
Senior Resident Medical Officer at the London Temperance Hospital.

INFLAMMATION of the parotid gland is occasionally observed after injuries to or operations upon the abdominal viscera, as well as during the course of certain specific fevers, dysentery, carcinoma, and phthisis. As a complication, however, of simple ulcer of the stomach the condition is comparatively rare, and scant allusion is made to it even in works which deal exclusively with diseases of the digestive organs. We find that during the five years 1898 to 1902 there were admitted into the medical wards of the London Temperance Hospital 153 cases of gastric ulcer, and that in three of these (2 per cent.) parotitis supervened while the patient remained under treatment. The actual frequency of the complication is, however, infinitely less common than these figures would suggest, since, owing to the great demands made upon the hospital accommodation by persons suffering from diseases of the stomach, cases of gastric ulcer are only admitted when suffering from hæmatemesis, perforation, or some

other important complication or sequela of the disease. The parotitis may arise either from a local infection of the gland through its duct or from general pyæmia. The former condition is by far the more common, and was responsible for the mischief in each of our three cases; but in another instance which came under our notice the formation of a small perigastric abscess due to leakage through the base of an ulcer was followed by fatal pyæmia, with secondary abscesses in the liver, lungs, and in the right parotid gland.

In each of our cases the gastric disease was chronic in character and the immediate cause of the patient's admission to the hospital was a severe attack of hæmatemesis. It is interesting to note that the parotid complication invariably ensued upon the fourth day after the hæmorrhage. In one instance the right gland alone was affected and the inflammation subsided under treatment, but in the other two the mischief became bilateral after an interval of three or four days and terminated in suppuration.

The first indication of the disease was a complaint of pain in the face or the ear, with limitation of the movements of the jaw and the development of a smooth, tender swelling in the region of the parotid. As the tumour increased in size the pain became more severe, and often radiated over the temple and the back of the head or down the neck, while in one case it was chiefly experienced in the ear and was accompanied by partial deafness. When suppuration occurred the skin over the tumour became tense and shining, and deep fluctuation could be detected on palpation. Occasionally the whole of the affected side of the face and scalp was œdematous. Unless promptly relieved by an incision, the pus showed a tendency to point behind the ramus of the jaw, to burrow into the neck, or burst into the external auditory meatus.

hæmorrhage and attained its maximum in twenty-four hours, after which it gradually declined until it reached its former level at the end of four days. Contrary, however, to most cases of abscess-formation, signs of suppuration did not manifest themselves until two or three days after the crisis of the fever. It is necessary, therefore, to watch the parotid swelling each day and to operate as soon as the existence of pus becomes evident, whether there be fever or no. The insidious manner in which pus may form was well illustrated in one of our cases, where, although the gland was incised and drained on the seventh day, a few days later, and without any access of fever, another abscess burst into the external auditory meatus and caused some trouble. When the other parotid is attacked a similar though less severe febrile reaction is observed.

As a rule, the state of the pulse affords a better criterion of the progress of the inflammation than the presence of fever. In each of our cases the onset of the pain and swelling was accompanied by a sudden acceleration in the pulse-rate, from about 80 to 116 beats per minute, with a further increase of rapidity when the fever subsided and suppuration occurred; indeed, it was not until the discharge had practically ceased that the pulse regained its normal rate.

During the progress of the disease, the patient complained of great prostration. The mouth and tongue were extremely foul, and the inability to open the mouth rendered it difficult to cleanse the buccal cavity. When the tension in the inflamed gland became severe partial deafness was present on the affected side, and in one case facial paralysis developed, apparently from stretching of the nerve, and did not subside until convalescence was established.

*Causation.*—Many theories have been put forward to explain the occurrence of parotitis after abdominal operations, and some authorities still seem to incline to a belief in a reflex nervous influence; but in the variety which occasionally ensues after hæmorrhage from the stomach we are convinced that the exciting cause is invariably to be found in an ascending infection of Stenson's duct. Our reasons for this are shortly as follows: (1) The parotid inflammation is invariably preceded by foulness of the mouth and never occurs if the buccal cavity is maintained in a clean and moist condition; (2) it is rarely seen in cases which are permitted throughout the whole course of the treatment to drink milk or partake of other forms of food, while it is unduly frequent in those that are nourished entirely by the rectum, all the cases that have come under our own observation having belonged to the latter category; (3) the side which is first affected seems to be determined to a great extent by the position assumed by the patient when in bed, the gland usually in contact with the pillow being that commonly attacked. Subsequently, when it becomes necessary to recline upon the opposite side owing to the painful swelling of the face, the other parotid is usually implicated. (4) A bacteriological examination of the pus obtained from the abscess always shows a mixed culture, the principal elements of which (staphylococcus pyogenes aureus and micrococcus lanceolatus) are also abundantly present in the thick secretions of the mouth.

*Treatment.*—The fact that parotitis occasionally ensues after severe hæmatemesis renders it important that special measures should be adopted to prevent its occurrence in such cases. In every instance, therefore, the state of the mouth requires immediate attention, and an effort must be made to stimulate the secretion of saliva. As a rule, constant cleansing of the mouth and tongue with a moderately strong solution of Condy's Fluid is most efficacious, but one of listerine (2 per cent.), resorcin (10 per cent.), or sulphurous acid may be employed if preferred, especial care being taken to thoroughly cleanse the spaces between the upper teeth and the cheek. In order to induce a secretion of saliva the patient should be directed to chew a piece of horseradish or pellitory root at intervals, to keep a pebbie in the mouth or to suck an indiarubber ring or teat. Sometimes the mastication of a piece of raw meat or gargling the mouth with a dilute solution of

The febrile disturbance that accompanied the parotitis was almost identical in its general features in the three cases, its course in the two instances where suppuration took place being represented in the annexed chart. It is interesting to note that the temperature began to rise on the fourth evening after the

a mineral acid is also of value as a sialagogue. If the inflammation has already set in the parts must be well fomented, and the pus should be evacuated as soon as its existence can be detected.

## A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

By WILLIAM J. THOMPSON, M.D., F.R.C.P.I.,  
Physician, Jervis Street Hospital, Dublin.

THAT acute yellow atrophy of the liver is a comparatively rare disease in this country is sufficiently demonstrated by the fact that no case has been reported at any of the sections of the Royal Academy of Medicine in Ireland since its inception twenty-one years ago. Murchinson, in his writings about this disease, stated that during a period of nine years, and out of a total number of 27,000 patients admitted into the London hospitals, he had only seen one case, and Dr. Wickham Legg could only trace one case in the records of St. Bartholomew's Hospital for a similar period.

It is an interesting as well as an historical fact, according to Dr. William Hunter, of Charing Cross Hospital, that it was Dublin physicians who, in the beginning of the last century, first in this country made observations about the disease—Cheyne and O'Brien in the year 1818 and Marsh, four years later; Morgagni had previous to this described cases presenting features of the disease. The first accurate clinical account recorded was that by Bright in the year 1836. He described the changes which took place in the liver as "a diffuse inflammation affecting more the glandular portion than the connective tissue, leading to great diminution in the size of the organ and accompanied by intense jaundice, severe nervous symptoms and often a hæmorrhagic tendency." Two English observers—Busk, in the year 1845, and Handfield Jones two years later—accurately described the characteristic microscopic appearance of the degenerated liver cells, and about the same time Continental investigators confirmed these observations and added more to what had already been made known.

The patient, E. B., was admitted into Jervis Street Hospital on August 24th last. She was a well-nourished woman of medium height and build, with dark hair and dark complexion, æt. 27. She was born in Dublin and had a good personal and family history. She had been married five years, had three children, the youngest of which was four weeks old; the other two, aged respectively 4 and 2 years, were strong and healthy. She had not had any miscarriage, nor was there a history of a rash or sore throat, so that syphilis as a cause must be excluded. Her husband, a labourer by occupation, was not always steady or at regular work, which necessitated her doing washing, and in this way she contributed to the support of her family. She had not been in the habit of taking either porter or any other stimulant. She resided in a tenement house situated in one of the most congested parts of the city, where the surroundings could not be anything other than detrimental to a robust state of health. While carrying her last baby she enjoyed average health, as she did on the two former pregnancies. Parturition seemed to have been normal and she was able to be up and about at the end of one week, and, as with the other two children, she nursed this child. In the beginning of the third week after her confinement, she felt sickness of stomach, loss of appetite, languor and the jaundice first appeared three weeks after child-birth. A week later, she first came under my care. At that time there was nothing in her condition to suspect anything other than an ordinary case of catarrhal jaundice. The liver dulness was not affected, no hardness or resistance of the organ could be detected and the gall-bladder was not distended; there was no pain on pressure. The tongue was thickly coated, enlarged, flabby, and indented with teeth marks—the teeth were exceptionally good; the tonsils were normal and no enlarged glands could be found. The abdomen was soft and flaccid, no rigidity

at or about the liver region, all the abdominal organs seemed normal, as also the heart and lungs. There was marked constipation and more sickness of stomach perhaps, than one usually gets in a simple case. The skin and mucous membrane presented all the appearance of a well-marked case of jaundice, as also did the urine. The quantity of urine passed per day was below the average, 35 oz. Urates were abundant there was a slight trace of albumin, no sugar, sp. gr. 1022, and the quantity of urea was less than normal. At this time leucin and tyrosin were not looked for. There was one other symptom patient complained of on admission—*viz.*, a shooting, acute, spasmodic pain lasting only a short time, apparently in the liver. She stated that the pain was deep-seated and scarcely ever occurred in the exact place a second time, and her description of the pain was as it were the stab of a sharp instrument. External pressure had no effect in either relieving or increasing it, nor did a deep breath affect it. All through her illness this symptom was prominent and towards the end became sometimes so severe that she had to cry out. Her temperature was normal and pulse 62 per minute. Stools typically those of jaundice.

For the first week in hospital this patient seemed to improve, took light nourishment well; the tongue became cleaner and the jaundice was apparently not so intense. The bowels, however, required strong purgatives. There was no trouble with the breasts, as the milk ceased coming at once, although she had been suckling her child until her admission. During her second week in hospital the patient did not feel so well, the nausea and epigastric discomfort became very marked, the bowels more stubborn and the jaundice more intense. From this until her death the patient got gradually worse, vomiting became almost incessant, the liver dulness diminished in area, and it was now found the amount of urea was diminished to about half what it was on admission and leucin and tyrosin were present. The temperature now became irregular, varying from 96.5 to 102°, and the pulse intermittent and fluctuated between 80 and 120. There was no direct relationship between the temperature and pulse; when the temperature was high, the pulse might be low and *vice versa*.

At the end of the third week in hospital cerebral symptoms developed; she gradually became drowsy and semi-conscious, was restless and had slight delirium—the jaundice became very intense and appeared as a greenish hue; the tongue became dry and brown, and the amount of urine passed diminished to 13 oz. per day. The liver dulness practically disappeared in front and only posteriorly could it be slightly detected. She remained in this condition for three days, but gradually becoming more unconscious and weaker, and died about four and a half weeks after the jaundice first appeared. The vomiting was always gastric; at no time had she any hæmatemesis, mælena, or any other hæmorrhagic manifestations.

In the *post-mortem* room the body was not much wasted considering the severity of her illness and the small quantity of nourishment she was able to make use of. On opening the abdomen there was found a small quantity of greenish-coloured fluid. The liver, instead of presenting as usual, was small, baggy-like and collapsed, and could only be seen by its being kept in position by the suspensory ligament. When removed it felt soft and spongy-like, with a wrinkled capsule and weighed 29 oz. The stomach was small, and on opening it the mucous membrane was found to be pale and apparently healthy. The other abdominal organs seemed to the naked eye normal. The spleen, pancreas, and the kidneys seemed healthy in size and on section. The uterus was normal and there was a small ovarian cyst about the size of a marble. None of the abdominal glands were enlarged. The heart and lungs were healthy and there was not any fluid in the pleural cavity or pericardium. I did not get an opportunity of examining the brain.

The clinical points of interest about this case are:—

1. The rather protracted course—about four and a half weeks, although Hunter in his twenty-nine

collected cases gives nine, or 31 per cent., as running a course of from three to eight weeks.

2. The acute, short, spasmodic liver pain which was persistent throughout.
3. The total absence of any hæmorrhagic symptoms.

ABSTRACT OF THE  
**Bradshaw Lecture**  
ON THE

**TREATMENT OF CANCER. (a)**

By A. W. MAYO ROBSON, F.R.C.S., Hon.D.Sc.,  
Vice-President of the College.

PREVENTIVE OPERATIONS.

*Precancerous Conditions.*—The so-called precancerous stage of malignant disease may be due to disturbances of nutrition, to previous injury, to congenital defect, or to other departures from the normal conditions.

Senility and decadence of tissues which have passed the period of their usefulness and are about to undergo physiological rest are predisposing factors. Predisposing conditions also exist in certain parts of the body where embryological vestiges or rests are found, and in certain regions, as the pylorus and the cæcum, and at the lines of junction of skin and mucous membrane.

In certain situations precancerous conditions can be readily recognised, especially in the tongue, lips, larynx, uterus, and the skin, suggesting strongly that cancer is a new implantation on a prepared ground. Probably, if we could only find it, every cancer, whether external or internal, follows on a precancerous condition. The liability of benign tumours, especially on epithelial surfaces, to undergo malignant changes is well recognised, hence the removal of such is generally advisable.

A general acceptance of the view that cancer has usually a precancerous stage, and that this stage is one in which operation ought to be performed, would be the means of saving many useful lives, for it would lead to the removal of all suspicious epithelial conditions before the onset of cancer. I hold that the arrest or removal of known causes as well as the abolition of discoverable precancerous conditions, whenever or however occurring, constitute true preventive treatment.

*The Gall-Bladder and Liver.*—The lecturer said that facts recorded by himself and by Zenker, Courvoisier, Schroeder, Beadles, and Rolleston established an undoubted relationship between cholelithiasis and cancer of the gall-bladder and ducts.

As gall-stones produce characteristic symptoms, and are therefore as a rule diagnosed early, and as they can be removed before serious complications have supervened with extremely little risk (in my experience, extending over some hundreds of operations, less than 1 per cent.), the preventive treatment for cancer of the gall-bladder is obviously removal of the source of irritation.

So impressed am I with the importance of this view, that although I know the symptoms of gall-stones, which frequently depend on the associated catarrh, can often be relieved for a time by general treatment (though the gall-stones producing the catarrh cannot be removed by medicine), yet I consider it wise to recommend their early removal, not only because it can safely be done, but also because the symptoms are likely to recur and lead to other complications, and not least important because in a considerable percentage of such cases malignant disease will supervene if the irritation be not removed.

*The Mammary Glands.*—In the breast there are certain well-known precancerous conditions, such as eczema of the nipple (first described by Sir James Paget as a precursor of duct cancer), chronic inflammatory enlargements (the chronic cirrhosing mastitis of Billroth, the interstitial mastitis of English pathologists), cysts and adenomata, and last, but not least, induration following on injury. Many of these conditions will, if

(a) Delivered before the Royal College of Surgeons of England on December 1st, 1904.

properly and seriously attended to, yield to treatment. Patients have usually themselves to blame for ignoring what they seem to think are trifling ailments, though sometimes the medical attendant may, to avoid frightening his client, make light of the condition. I would say far better to alarm and cure than to lull into a false sense of security, and have to counsel operation later when the conditions are less favourable for radical treatment.

If eczema of the nipple does not speedily yield to treatment, the nipple should be freely excised, and with it the first portion of the primary ducts. If a chronic inflammatory swelling does not disappear under adequate treatment, the lobule or lobules involved ought to be removed, or, if general, the breast should be ablated. Cysts or tumours, even if simple, should be taken away, and if, on examination after removal, there is any suspicion that the simple stage is passed, the whole breast should be removed, and with it the nearest lymph glands.

It ought to be recognised that the watching of a doubtful tumour of the mammary gland until it becomes definitely malignant is an unjustifiable and a blameworthy procedure. Removal in this stage can be done without risk, and while the anxiety of the patient is relieved the fear of the development of malignancy is removed.

*The Stomach.*—Precancerous conditions of the stomach are, in certain cases, distinctly recognisable, and, if diagnosed and treated, might save many patients from carcinoma. As the stomach is one of the commonest sites of cancer, if even a percentage of cases can be saved from malignant disease by timely treatment a great advantage will have been gained.

Carcinoma occurs most frequently in those areas in which the ulcers chiefly lie. Whatever the frequency of the malignant change in chronic ulcer may prove to be, the fact of its occurrence should be an additional incentive to the earlier surgical treatment of ulcers which prove rebellious.

I firmly believe that greater regard for oral asepsis and more careful attention to the teeth would save much stomach disease, and I think one of the chief causes of the frequency of gastric ulcers among the mill operatives of Yorkshire and Lancashire is carious teeth with its accompaniment, oral sepsis. I am also firmly convinced that the early and thorough medical treatment of gastric ulcers and the surgical treatment, either by gastro-enterostomy or excision of those that prove rebellious, would do much to lessen the amount of cancer of the stomach.

*The Pelvic Organs of Women.*—Cancer is perhaps more commonly noticed to supervene on a recognisable precancerous condition in the uterus than is observable in any other organ, and the frequency with which cancer develops in multiparæ, and especially in those who have had lacerated cervix, points distinctly to cause and effect.

The frequent advent of cancer on old scars is well known in various parts of the body, especially in those placed where their nutrition is liable to disturbance, as in the scars of burns. Now in the cervix uteri we see the scars of old ulcers, the result of laceration in childbed, often remaining untreated for years and leading to constant distress, with backache, leucorrhœa, and other well-known symptoms. Only a few months ago, I saw a case of this kind pass from the simple to the malignant stage, an operation having been declined on both occasions when I saw the patient, and only consented to six months later, after epithelioma had developed. Cancer of the cervix uteri is infrequent in sterile women whose cervical canal has not been subjected to the lacerations which often occur in parturition, whereas cancer of the body of the uterus is of equal frequency in those who have and have not borne children. Most careful attention to post-puerperal conditions and the performance of the simple operation described by Emmett would remove this source of danger in a great number of cases.

Uterine adenomata doubtless predispose to cancer

of the uterus, and the co-existence of mucous polyp and epithelioma is not without its significance, as early operation in such cases would probably prevent the onset of malignant disease. The malignant degeneration of uterine myomata is probably commoner than is generally supposed, and on several occasions I have removed what was supposed to be a simple myoma of the uterus, and found a sarcomatous change going on. As myoma of the uterus can be removed by hysterectomy with very small risk, I make it a rule, whenever a myoma begins to enlarge at or near or after the menopause, to advise its removal; while I hold with those writers who recommend the removal of "fibroids" whenever the symptoms of hæmorrhage, pressure, or pain seriously interfere with health or comfort. Surely, it is better to accept a risk of 2 to 3 per cent., with a view to the removal of a disease that in itself promises to endanger life, and which in a certain percentage of cases undergoes a malignant change, than to have to operate when cancer or sarcoma have already developed, and when the risk of operation will be seriously increased and the chances of permanent cure very much lessened.

The fact that malignant disease of the ovary begins in the first place as a small tumour (often cystic), and that cystic disease is apt to undergo malignant degeneration, affords good ground for recommending operation at an early stage in the case of any ovarian tumour, when perchance the disease may be caught in a precancerous condition; or should malignant disease have already commenced it will be limited and removable.

*The Intestines.*—Though, on account of its inaccessibility to direct examination, a precancerous condition is difficult to diagnose in the upper intestines generally, it will be found in many cases that there have been premonitory symptoms pointing to ulcer or colitis. Irregular pains, the passage of mucus or blood, and constipation, possibly alternating with diarrhoea, should rouse a suspicion of organic disease, and lead to a careful physical investigation that may reveal irregular peristalsis or possibly a tumour, which, even if not caught in the precancerous stage, will be recognised, and treated in the incipient and curable stage of cancer.

Any disease high up in the rectum or in the lower loop of the sigmoid flexure is quite out of reach of the finger, and cannot be palpated through the abdominal wall unless of considerable size; here, as a rule, disease has had to be diagnosed by symptoms alone, and symptoms sufficiently definite to warrant exploration only come on when the disease has passed the most favourable time for radical treatment. Fortunately, by means of the electric sigmoidoscope invented by Professor Strauss, of Berlin, to which attention was drawn by Mr. P. L. Mummery, a clear view of every portion of the inside of the bowel may be obtained, even as high as the top of the sigmoid flexure, without inconvenience or danger to the patient. It will do away with the need for exploratory operations in this region for mere diagnostic purposes, and will enable disease to be more frequently removed in the precancerous condition.

In the rectum the earlier treatment of hæmorrhoids and ulcers and of all chronic sources of irritation is obviously rational and advisable, and may sometimes be the means of preventing the onset of malignant disease.

#### RADICAL TREATMENT OF CANCER.

By the radical treatment of cancer I mean the entire removal of the disease at an early period, together with a wide margin of healthy tissue, and, if practicable, the nearest lymphatic glands.

In estimating what may be done for cancer by radical treatment, I do not think it sufficient simply to consider the mortality of any special operation, as has so often been done, when operative success was used as a cloak to mask therapeutic failure, but I want to know the ultimate results, after the lapse of years, of operations undertaken at an early stage of the disease, where the cancer had been freely and widely excised. Nor do I think it fair to surgery to average the statistics of all surgeons, or even of all hospitals, but rather to select the statistics of operators interested in special lines of work who can show what can be done in their

own particular region. The levelling process should, from my point of view, be a levelling-up to the best and not an averaging down to the worst.

*Cancer of the Breast.*—In my experience in hospital and in private practice I can point to a very large number of radical mammary operations, and I have been astonished to find how many, especially of the private cases where, through the kindness of the family physicians, I have been able to trace the after-histories, have survived beyond the three years' limit, and how many are still living and well many years after operation.

Of the 62 operations I have done in private practice for cancer of the breast, there was no operative mortality, 23 survived the three years' limit, and 20 are now alive and well at periods up to twelve years after operation; 5 died from other diseases without recurrence of cancer, 1 twenty years after the major operation, 28 had recurrence, though in 8 it was over three years subsequent to operation; 8 could not be traced.

My early operations were not so thorough as those done in later years, otherwise I feel sure that the recurrences would have been even fewer.

To Dr. Halstead, of Baltimore, belongs the distinction of carrying operations for cancer of the breast to their widest limits at the Johns Hopkins Clinic, of which the following is a brief account of the ultimate result of 161 patients admitted with operable primary tumours of the breast, on whom complete operations were performed between June, 1889, and August, 1890.

In August, 1902, 60 patients were living and cured 7 had lived over three years and died from other causes, and 2 had died from other causes with the three year limit, autopsy showing no signs of recurrence. This gives 60 cases, or 42·8 per cent., positively cured. An analysis of the 161 patients shows that 83, or 51·5 per cent., survived the three year limit.

The operations performed consisted of complete excision of the breast, both pectoral muscles and axillary contents in one piece, and complete excision of the contents of the supraclavicular fossa. During thirteen years 305 patients with primary and 38 with secondary tumours were admitted to the clinic, and of these it is worth noting that 83, or 27·2 per cent., were inoperable, owing to delay in seeking surgical assistance. It is also of interest to note that in no case was local recurrence or internal metastasis observed after three years.

Mr. Bryant has recorded from his own experience 46 cases of amputation of the breast for cancer, in which the patients survived the primary operation from five to thirty-two years.

My colleague, Mr. Watson Cheyne, adopting a most thorough and radical operation on lines similar to those of Professor Halsted, shows very satisfactory results. He says that, taking the average of all cases operated on, favourable or otherwise, something like 50 per cent. will remain well for a number of years, and in these cases, in which the tumour is small and well limited, and the glandular infection is slight, the proportion of successes will be considerably greater. In these views I most thoroughly agree.

Cancer of the breast, if operated on early and with thoroughness, is by no means the incurable disease that many still think; in a very large percentage, 50 or more, the patients may look for over three years' respite; and in 40 per cent. to a much longer period of freedom, and many to a genuine cure.

#### RADICAL TREATMENT OF CANCER OF THE STOMACH.

It was only in 1879 that Péan performed his first pylorotomy for cancer of the stomach, and in 1881 that Billroth did the first successful operation; before that time, and long after by many, the disease was held to be incurable. At first sight it would appear to be hopeless to expect that eradication of the disease could be possible in an organ situated as the stomach is and so freely supplied with blood vessels and lymphatics; yet a careful study of its anatomy shows it to be fixed only at the cardiac extremity, and with the exception of that part the remainder is as freely accessible for

operative purposes as the intestines; moreover, the disease if caught early can be completely removed. I can point to a number of patients in good health on whom I performed partial removal of the stomach years ago, and to one especially.

A man, *æt.* 42, from whom I removed the whole stomach, except a small portion of the dome and the cardiac orifice, four years ago. He was reported last month to be robust and well, to be able to take quite ordinary diet, and to have followed his business without any disability from within two months of his operation up to the present time.

In another case, a woman, *æt.* 54, a partial-gastrectomy was performed at the same time as removal of the gall-bladder, both organs being involved in cancer. She remains well now in the fifth year after operation. In another case, a woman of 50 remains well nearly four years after the removal of the centre of a cancerous hour-glass stomach, the proximal and distal healthy portions having been joined over a decalcified bone bobbin.

Whenever a patient at or after middle age complains somewhat suddenly of indefinite gastric uneasiness, pain, and vomiting, followed by progressive loss of weight and energy, and associated with anæmia, the possibility of cancer of the stomach should be recognised, and if no improvement takes place in a few weeks at most, an exploratory operation is more than justified. Our diagnosis can only be rendered certain by a digital examination, which may be effected through a small incision that can, if needful, be made under cocaine anæsthesia with little, if any, risk.

Removal at any early stage offers good prospects of immediate recovery and a fair probability of cure, and excision of even a considerable portion of the stomach may be something more than a palliative operation. Although it is better to have cancer diagnosed and operated on early, yet we need not take the pessimistic view that if a tumour be manifest it is too late to perform a radical operation.

#### CANCER OF THE TONGUE.

I remember as a student seeing a number of removals of the tongue by the *écraseur*, there being no question of removal of the glands or of the floor of the mouth. In nearly every case recurrence took place within a few months, and the operation was falling into disfavour, when Whitehead invented his operation of removing the tongue widely with scissors, and Kocher's operation of clearing out the tongue, floor of the mouth, and the submaxillary and lymphatic glands also came to be practised.

These operations brought a marked change, and it was soon found that a good percentage of patients operated on remained free from disease for some time, and others were really cured. I can point to a case, well, seven years after operation, to another five years, and to others over three years, and it is of interest to note that in these cases very good power of speech is retained by the patients.

If only diseases of the tongue were attacked in the precancerous stage: if only this were done more frequently, and if, even when cancer had developed, time were not lost in dosing patients with iodides week after week until the disease has extended too widely, there would be a much brighter tale to tell.

#### CANCER OF THE LARYNX.

What could at first sight appear more hopeless for radical treatment than cancer of the larynx, which formerly used only to be treated palliatively by tracheotomy, later was removed by the formidable operation of complete laryngectomy with a very high mortality, and, lastly, has been most successfully dealt with, when seen early, by the much more simple operation of thyrotomy and removal of the diseased part, as advocated by Mr. H. T. Butlin in 1889? My friend, Sir Felix Semon, has been kind enough to give me the statistics of his thyrotomy operations, the results of which are remarkable, and which prove up to the hilt the special point which I want to insist on in this lecture, that if we get cancer cases sent to us sufficiently early, operation is not merely palliative, but curative.

#### RADICAL OPERATIONS FOR CANCER OF THE INTESTINE.

Intestinal cancer is nearly always columnar-celled carcinoma, and even when it has advanced to a fatal issue, the disease is limited to the gut in over 40 per cent. of cases. I believe that all the cases in which the disease is limited ought to be capable of cure by enterectomy if operated on early. It should also be borne in mind that even if enlarged glands be present it does not necessarily mean that they are cancerous, for clinical and pathological experience has shown the contrary. In some of my own cases, enterectomy, despite the presence of enlarged glands, has resulted in cure.

In all chronic ailments associated with dyspepsia or constipation or abdominal pain, a careful examination of the abdomen should be made in order to discover disease at the earliest possible moment, for to wait until obstruction occurs is to lose the favourable moment, and to add very seriously to the danger of any operation.

In operating I make a very wide sweep of the disease, going several inches beyond the growth above and below, and removing the lymphatics and glands belonging to the affected parts of the bowel as far as possible. Personally, I prefer to use my decalcified bone bobbin, but I have employed with success the simple suture and the Murphy button, though I still feel that by means of the bobbin used as a temporary splint around which to apply sutures, I can perform a safer operation than by any other method.

#### CANCER OF THE RECTUM.

This is an affection that of all others lends itself to a radical cure, for it can be recognised early. It is safe to say now that there is no part of the alimentary canal that cannot be reached for a radical operation, for even in the rectum that part which cannot be reached from the perinæum can be got at from above by opening the abdomen with the patient in the Trendelenberg position, as was so ably demonstrated by my friend, Sir Charles Ball, from this chair last year; and, fortunately, there need be no doubt about the nature and extent of the disease in this region, for the electric proctoscope enables the lower bowel to be examined by the eye without difficulty to a height of 30 centimetres.

Among other notable examples of radical cure, I can point to one patient living in perfect health and with good control of the bowel, from whom I removed a cancer of the rectum by proctectomy twelve years ago; to another, eight years; and to others who are well and enjoying life several years after operation.

#### CANCER OF THE GALL-BLADDER AND LIVER.

If the favourable precancerous period has passed, and malignant disease has actually supervened, can anything be done for the sufferers?

At first sight it would appear that cancer of the gall-bladder is an utterly hopeless disease, especially when it has extended to the liver. I have, however, operated on 12 cases of cancer of the gall-bladder, and in 11 the disease extended to the liver, forming the tumour of some size. Of these 12 cases 10 recovered from the operation and lived for varying periods. Five of these patients are at the present time alive and in good health at periods of 5½, 5, 4½, 4, and 1½ years respectively subsequent to operation. These were cases of primary cancer of the gall-bladder due to the irritation of gall-stones, and the liver growth was due to extension by continuity, not to secondary deposits in that organ. In one case I was able to remove as much as half a pound of the liver with success.

*Cancer of the Lip.*—Even if the precancerous stage has passed, a free removal of the disease at an early stage and while it is still local enables a very good prognosis to be given.

*Cancer of the Penis.*—In epithelioma of the penis amputation yields a cure in one-third of the cases operated on.

*Cancer of the Uterus.*—Much may be done to prevent this dread disease by careful surgical treatment, and that without risk. Even when the precancerous stage is passed, if women could be educated to the fact that were they to seek advice earlier, and, in fact, whenever

an abnormal sanguineous discharge appears, apart from a menstrual period, in a very large percentage of cases the cancer would be recognised in its incipient condition when the disease is local, and removal could be carried out and cure effected.

It seems to be most desirable that some crusade against the neglect of the well-known early symptoms of uterine cancer should be undertaken, and that women should be warned how important it is for them to consult their medical attendants at an early stage, when, in case of doubt, a small piece of tissue can easily be removed and examined microscopically.

In conclusion, Mr. Robson remarked that his purpose would have been served if he had been able, in however small a degree, to convince those who had the chance of seeing patients in the early stages of their illness, that in many cases cancer could be prevented by treatment in the precancerous stage; that even when cancer had developed, if it were seen early and thoroughly removed, it was frequently a curable disease; and, lastly, that even in the later stages much might be done by surgical treatment to give real relief.

Was it too much to hope, he asked, that some of the views he had enunciated might filter through the profession to the public, and serve to convince them that until a true prophylactic for cancer was discovered, they would be consulting their own interests best by seeking medical advice earlier, since to trifle with their ailments in the early stages was to lose the favourable moment and ultimately to hear the verdict—alas, too often pronounced—too late!

#### Royal Free Hospital.

The following scholarships have been awarded at the London (Royal Free Hospital) School of Medicine for Women: St. Dunstan's Medical Exhibition of £60 for five years to M. Muncey, the School Scholarship of £30 to E. M. Morris, two Mackey prizes of £20 each to E. Griffiths and E. H. Lepper, the Fanny Butler Scholarship of £14 10s. to G. M. Stagg.

#### Mater Misericordiarum Hospital, Dublin.

At a meeting last week of the Medical Board of the Mater Misericordiarum Hospital, the following appointments were made:—Temporary Assistant Surgeon, Mr. Denis Keane, M.B., B.Ch., B.A.O.R.U.I.; House Physicians, Drs. Thomas Barry, M.B., B.Ch., B.A.O.R.U.I., and William L. Murphy, B.A.Cantab., L.R.C.P.I., L.R.C.S.I.; House Surgeons, Messrs. Thomas Cronin, M.B., B.Ch., B.A.O.R.U.I., Richard Flood, M.B., B.Ch., B.A.O.R.U.I., and Michael Keane, L.R.C.P.I., L.R.C.S.I.

#### St. Thomas's Hospital.

THE following have been selected as House Officers from yesterday (Tuesday):—Resident House Physicians:—B. Higham, M.R.C.S., L.R.C.P. (*Extension*); W. Haward, M.B., B.S.Durh., M.R.C.S., L.R.C.P. (*Extension*); A. G. Gibson, B.A., M.B., B.Ch.Oxon., B.Sc.Lond.; K. Takaki, M.R.C.S., L.R.C.P. House Physicians to Out-patients:—R. E. Whitting, M.A., M.B., B.C.Cantab.; F. A. Brodribb, M.R.C.S., L.R.C.P. Resident House Surgeons:—H. S. Bennett, M.R.C.S., L.R.C.P.; N. C. Carver, B.A., B.C.Cantab., M.R.C.S., L.R.C.P.; A. C. Birt, M.R.C.S., L.R.C.P.; G. T. Birks, M.A., M.B., B.C.Cantab. House Surgeons to Out-patients:—H. A. Kisch, M.R.C.S., L.R.C.P.; G. R. Footner, B.A.Cantab., M.R.C.S., L.R.C.P.; R. E. G. Gray, M.A.Cantab., M.R.C.S., L.R.C.P.; J. C. F. De Vaughan, M.R.C.S., L.R.C.P. (*Extension*), Obst. House Phys.:—(*Senior*) H. I. Pinches, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P.; (*Junior*) E. W. Parry, M.R.C.S., L.R.C.P. Ophthalmic House Surgeons:—(*Senior*) H. S. Stannus, M.B.Lond., M.R.C.S., L.R.C.P.; (*Junior*) A. B. Bradford, M.B., B.S.Durh., M.R.C.S., L.R.C.P. Throat Department:—C. N. Sears, M.B., B.S.Lond., M.R.C.S., L.R.C.P.; D. K. Coutts, M.R.C.S., L.R.C.P. Skin Department:—W. L. Harnett, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P. (*Extension*); F. M. Bulley, B.A.Cantab., M.R.C.S., L.R.C.P. (*Extension*); Ear Department:—T. Guthrie, M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P. (*Extension*); L. E. C. Norbury, M.R.C.S., L.R.C.P.

## Clinical Records.

### ROTUNDA HOSPITAL, DUBLIN.

#### A Case of Caesarean Section.

Performed by E. HASTINGS TWEEDY, M.D., &c.,  
Master of the Rotunda Hospital.

[Recorded by A. N. Holmes, M.B., B.Ch., B.A.O.U. nrv. Dub., and L.M., Assistant Master, Rotunda Hospital.]

IN view of the fact that Caesarean section is so great a rarity in this country, it may prove of interest to cite the following case, which occurred recently in the Rotunda Hospital.

A. O'R., primipara, æt. 29, was admitted to the hospital on Sunday evening, November 6th, at 8 p.m. She was a very small woman, her height being 4 ft. 3 in. and her limbs and pelvis presented well-marked rachitic deformity.

On inquiry she stated that, as far as she knew, she was up to full term, and, further, that the membrane had ruptured several hours before she came into hospital. She was not having any pains.

On inspection, there was seen a prominent tumour over the symphysis pubis, which palpation proved to be the head, freely movable. Fœtal movements were also felt and the heart heard. A vaginal examination was made and the promontory felt with the greatest ease low down, and the os, which was high up, admitted one finger. Pelvimetry was at once done, and the following measurements obtained:—Conjugata vera, 6 cms.; transverse, 11 cms.; interspinous, 25 cms.; intercrystal, 24.8 cms.; extern. conjugata, 17 cms.

On finding these, Caesarean section presented itself as the only means of delivery. As the patient showed no signs of labour, the following morning at 10.30 a.m. was fixed on for operation should no indications for earlier interference arise.

In the morning the patient had one or two slight pains about 9.30 a.m. At 10.30 a.m., the master, Dr. Hastings Tweedy, assisted by Sr Arthur Macan and the two assistant masters, opened the abdomen by a six-inch incision, having the umbilicus as centre. An assistant kept the incised wound in close apposition to the uterus to guard against the possibility of fluid entering the abdominal cavity. The uterus was now rapidly laid open by a five-inch incision along the interior aspect of the upper uterine segment. In doing this the placenta was encountered and occasioned smart hæmorrhage. Without making any effort to control this, a limb was seized by the hand and the fœtus having been rapidly removed, was handed over to the care of an assistant. The uterus with its contained after-birth, was now delivered from the abdominal cavity, and all the hæmorrhage from it controlled by the hand of an assistant tightly compressing the cervical region. Another assistant temporarily closed the upper part of the abdominal incision by means of a bullet forceps, whilst a moist sterilised towel protected the uterus from the skin. During the progress of these procedures, the master was engaged in detaching the after-birth, and it was curious to note the rapid and marked thickening of the muscle which took place despite the absence of uterine contraction, a proof of the independence of the processes "contraction" and "retraction."

The uterine wound was now stitched in a careful and deliberate manner with No. 3 antiseptic silk interrupted sutures. These were placed at close intervals and were not drawn too tightly. A tear had taken place during the extraction of the child, which extended some distance from the original incision and required more than ordinary care in its closure. The uterus contracted well, stimulated by hot towels, and the abdomen was closed in three layers—peritoneal, fascial of continuous silk, and a subcuticular cutaneous of silkworm-gut. Throughout the operation rubber gloves were worn by all.

The puerperium has been quite uneventful. The suture was removed on the fourteenth day, leaving a perfectly healthy scar, and the patient has been able to nurse her baby from the third day.

## Transactions of Societies.

### ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD NOVEMBER 25TH, 1904.

The President, H. C. EARL, in the Chair.

THE PRESIDENT exhibited a small "VILLOUS TUMOUR OF THE BLADDER."

A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

Dr. W. J. THOMPSON stated that E. B. was admitted to Jervis Street Hospital on August 24th, 1904, a few weeks after her confinement, and suffering from jaundice one week. She was *æt.* 27, married six years, had three children; her family and personal history were good; had a hard life and lived in a tenement house in a congested part of the city. On admission, case seemed an ordinary catarrhal one; no enlargements of liver, all the organs normal, urine contained a slight trace of albumin. She seemed to improve the first week, but got worse during the second week. Nausea became almost constant and acute; sharp, spasmodic pains in liver became severe. During third week liver dulness greatly diminished. Leucin and tyrosin were detected in the urine, and at same time urea was diminished. At end of third week severe nervous and cerebral symptoms developed and she died three days afterwards, four and a half weeks after first sign of jaundice. At the *post-mortem* examination the liver was found to be small and soft, and only weighed 29 oz. All the abdominal organs were in a healthy condition, save for a small ovarian cyst. The clinical points of interest are: (1) The protracted length of the attack, four and a half weeks; (2) the acute, spasmodic, and agonising liver pains; (3) no hæmorrhagic manifestations.

Prof. E. J. McWEENEY then described the character of the specimen as follows: Liver weighing 29 oz., small, very soft and pulpy; capsule wrinkled, pale red with yellowish mottlings. On section, mostly reddish with bright yellow patches, lobular marking obliterated. Dimensions of right lobe, 6 in. from side to side,  $5\frac{1}{2}$  in. from before backwards,  $1\frac{1}{2}$  in. thick. The left lobe was at most only half an inch thick. Gall-bladder normal. The microscopic examination was made by means of teased preparations, frozen and paraffin sections. It showed complete necrosis of the liver cells; patches of round-cell infiltration, which still preserved their nuclear staining; patchy pigmentation of the liver cells with yellow granular matter which did not give an iron reaction (bile); moderate fatty degeneration; and the presence of minute, yellowish-brown globular concretions in groups and rows. These were very abundant in the tissue, and varied from  $12\mu$  to  $30\mu$  in diameter. Some of them seemed radially cleft, others were coated with a prickly layer of minute needle-shaped crystals, whilst others presented obscure concentric striation. There were also minute colourless acicular crystals lying singly and in sheaves. These objects were doubtless crystals of leucin and tyrosin. The globules were soluble in alkalis and weak  $H_2SO_4$ ; insoluble in ether, alcohol, and chloroform; partly soluble in water. A few bacilli were demonstrable on the sections, and of the numerous culture-tubes inoculated, a few showed colonies. Study of the organisms, however, convinced him that they were merely ordinary putrefactive germs.

Prof. O'SULLIVAN said he remembered one case of the kind, which belonged to Dr. Wallace Beatty. He had some sections of it which resembled those shown considerably, but his were more advanced. He was not sure that he would have taken Prof. McWeeney's view of the condition of the liver cells, as he did not think the process was very far advanced. There was certainly not so much disintegration shown in the sections as in those of the case in his possession. The process seemed to be starting from the hepatic veins, the portal areas being less affected.

The PRESIDENT had seen portions of a liver from an undoubted case of this disease. There was a large

portion of the right lobe involved, and on section of this, more than half the affected portion was a brilliant red colour, and the rest an equally brilliant yellow. In the red area the liver cells had disappeared, and in the portal canals there was small round cell infiltration. In the yellow areas were cells which looked absolutely normal. He was surprised at the small amount of fat he found in the cells. He noticed in some parts of the yellow areas, where they bordered on the red, that the centres of the lobules were certainly more affected than the margins. The process seemed to be progressing from the centre of the lobule to the periphery.

Prof. McWEENEY, in replying, said he considered that the cells were completely necrotic, though their outlines were preserved. They did not give the ordinary nuclear stain. The protoplasm had stained diffusely with hæmatoxylin stain. The preparations showed no well-preserved liver cells. The yellow pigmentation was well marked in one of the sections. The bacteriology of these cases was very interesting, because it was very important to eliminate the theory of living bacteria. The generally accepted theory was that it was due to toxins. He had set going a number of aerobic and anaerobic cultures, but the material was not perfectly fresh. The anaerobic tubes remained sterile, and the aerobic showed some small white colonies which he considered unimportant. He cut some sections in paraffin, and found an occasional bacillus, which he thought were ordinary putrefactive organisms. He thought the toxæmia theory still held the field.

#### GLANDERS.

The SECRETARY (for Dr. E. F. STEPHENSON) read notes of a fatal case of "Glanders in a Man."

Mr. STORY and the PRESIDENT exhibited a "Glioma of the Retina," with microscopic sections.

#### GLIOMA OF RETINA.

Dr. MOONEY exhibited a specimen which was a right eye removed from a female child, *æt.* 3, for glioma retinae. Four months before admission to the Children's Hospital, Temple Street, the eye squinted, and for four weeks the pupil had been white and eye blind. The eye showed no irritation, nor was there pain, although the tension equalled + 2. No proptosis. Microscopically, the tumour showed usual appearances, much of it being necrotic and fluid, with spots of hyaline degeneration. The optic nerve was wholly invaded by gliomatous cells up to point of section, only the fibrous trabeculae remaining.

Prof. McWEENEY said he never saw a prettier example of infiltration of the optic nerve. The resemblance between the cells of the tumour and the nuclear cells of the retina was very striking. He agreed as to the rarity of finding tubes lined with epithelium. These tumours, when not necrotic, were formed of small, round nuclei, broken up here and there by patches of necrosis. In Dr. Mooney's case patches of hyaline degeneration could be seen. It was not so well marked in Dr. Earl's case.

Prof. O'SULLIVAN thought the resemblance to angio-sarcoma was due to the fact that the cells in the neighbourhood of the vessels were well nourished, while those away from them were not and therefore became necrotic. This should be borne in mind in examining all cases of angio-sarcoma. The cells thus seemed to exist as tubes round the vessels.

Dr. MOONEY, in replying, said he had omitted to mention that there were some calcareous spots in his specimen.

The PRESIDENT, in replying, said he agreed with Prof. O'Sullivan as to necrosis occurring in those cells which were far away from the vessels.

#### HÆMATOLOGICAL OBSERVATIONS ON A CASE OF MYELÆMIA.

Prof. E. J. McWEENEY described this case, and exhibited the spleen and bone-marrow, as well as numerous blood-slides and sections of the various organs. The patient was a man, *æt.* 41, an inmate of Mullingar District Asylum for the past six years, suffering from paranoia with hallucinations and delusions. After four years of good bodily health he began to lose weight and became unable to work. A large

abdominal tumour was then discovered and recognised to be the hugely enlarged spleen. Blood counts yielded reds, 2,680,000, and whites, 450,000. Despite rest in bed, good food, and open air, he became steadily weaker. There was slight fever. Anæmic symptoms never prominent, and hæmorrhages did not supervene till a few days before death, when he suffered from epistaxis and hæmorrhagic effusion into subcutaneous tissue of right thorax. The duration of the case from the discovery of the splenic tumour was fourteen months. The autopsy revealed the following chief points: Enormous enlargement of the spleen, which weighed 145 oz., was firm, dark red and homogeneous on section, and presented neither hæmorrhages, infarcts, nor whitish infiltrations. Marrow of long bones pink, fleshy, vascular, completely altered from its normal fatty state. Superficial lymph-glands not enlarged. Of the internal ones, the bronchial, omental, mesenteric, and celiac were slightly enlarged. There was slight obsolete tubercle in both apices. The liver weighed 138 oz., but showed no macroscopic change beyond slight nutmeg discoloration and marked hyperæmia. No leucæmic infiltration in any of the organs. The results of the histological examination were then given. Blood-films taken shortly before death showed: Polymorphs, 35 per cent.; myelocytes, 45 per cent.; transitionals, 3.5 per cent.; small lymphocytes, 2 per cent.; eosinophiles, poly and mononuclear, 14.5 per cent. A certain number of mast-cells were seen, and polymorphs with mitotic nuclei were readily found in the peripheral blood. Marrow films revealed giant-cells, myelocytes, eosinophiles of both kinds, large and small hyaline mononuclear and normoblasts in varying proportions. Megaloblasts were very few, and that class of cell was represented by forms with nucleus and discoplasm of megaloblastic type, but smaller than an ordinary red corpuscle. The speaker expressed his deep sense of obligation to Dr. A. Finegan, Resident Medical Superintendent of Mullingar Asylum, for permission to bring the case forward, and to Dr. W. S. Gordon, Assistant Medical Officer, for the very full clinical notes of the case.

Prof. WHITE said that the point which interested him most was the section which showed what was probably mitosis. He was convinced of the fact that mitoses did occur in the circulating blood under certain conditions.

Prof. O'SULLIVAN suggested the possibility that the giant-cells in the liver capillaries might have been marrow cells carried there.

Prof. McWENEY, in replying, said that the giant-cells were products of the endothelium.

#### NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

MEETING HELD AT SHEFFIELD, NOVEMBER 18TH, 1904.

DR. R. FAVELL, Vice-President, in the Chair.

THE Society passed a unanimous vote of hearty congratulation to the President, Sir William Japp Sinclair, on the honour recently conferred upon him by H. M. the King.

Dr. J. B. HELLIER, whilst showing a myomatous uterus removed by abdominal hysterectomy, mentioned that although the operation presented no difficulty and the patient made a good recovery, without any suppuration, an interesting complication occurred on the second morning after operation. The temperature rose to 100.6°, and the pulse to 140; there was acute abdominal pain with distention and hiccough, and a turpentine enema brought no relief. The distension was chiefly at the upper part of the abdomen, and it was therefore decided to wash out the stomach. On passing the stomach tube there was an immediate escape of gas, a large quantity of mucus was removed, and immediate relief was obtained. The lavage was repeated in the evening, and the symptoms abated from this time.

Dr. J. E. GEMMELL (Liverpool) read a short paper on a case of

#### CÆSAREAN SECTION FOR MYASTHENIA GRAVIS.

The case had been referred to him by Dr. W. B. Warrington, Physician to the Northern Hospital, who had described it from the physician's point of view in the *Medical Chronicle* for April, 1904. Dr. Gemmell remarked that the clinical feature of the disease is muscular weakness of some or all of the voluntary muscles, sometimes amounting to paralysis. After a prolonged rest these same muscles may respond to the will, but they again become rapidly exhausted. Soon after the patient's admission to the Northern Hospital it was found that she was pregnant, and that as the pregnancy advanced the disease became worse, until physical exertion of the slightest kind produced the greatest exhaustion and led to the onset of alarming dyspnoea. Labour was expected about October 20th, and the patient was admitted to the Lying-in Hospital on October 15th. During the first twenty-four hours she had four attacks of dyspnoea, each lasting five minutes, whilst for the first forty-eight hours she scarcely slept at all. Dr. Warrington had pointed out that if the patient did not succumb during the first stage of labour, attempt at the use of the secondary powers in the following stage would almost certainly bring on a fatal attack of dyspnoea. Dr. Gemmell decided to await the advent of labour and act as occasion might require. However, the dyspnoea increased in gravity, and on October 18th, it was found that the only respiratory movements were those associated with hiccough. Cæsarean section, as the speediest means of delivering the patient, was decided upon. The operation was rapidly carried out without any difficulty, and was followed by uninterrupted recovery and gradual improvement of the respiratory symptoms. Dr. Gemmell remarked that he had been unable to find any reference to the effect of parturition in advanced cases similar to this one. One patient with ocular paralysis became pregnant and became practically well of the paralyses. Another developed the disease when six months pregnant, improved, and then is recorded as a typical case three years later.

Prof. ARTHUR J. HALL (Sheffield) thought that the right and proper treatment had been carried out, and remarked that such an event as Cæsarean section was probably unique in the annals of myasthenia gravis. He referred to the rarity of cases of this disease, and to the constancy with which they were usually diagnosed as hysteria in their earlier stages, chiefly because of the extreme variability of the symptoms from day to day, or even from hour to hour. In a fatal case of the disease which he had recorded a few years ago in *Brain*, this variability was a striking feature: at one time the patient would walk fairly well, at another she would hardly be able to stand. After a sleep she would be able to speak clearly and to open the eyes widely, whilst as the day went on, her voice would become nasal and there would be marked ptosis. Even the sudden death of the patient from respiratory failure followed a day after she had seemed better than she had been for weeks.

After further discussion, Dr. GEMMELL said that the anæsthetic employed had been chloroform, very little being required. If such a case had been met with in the earlier stages of pregnancy, it would have been proper treatment to cut short the gestation.

Dr. JOHN W. MARTIN (Sheffield) read notes of a case of

DOUBLE OVARIAN PAPILLOMATOUS CYSTIC TUMOURS, with a large fibroid springing from the fundus uteri. The points of interest were: (1) There was not much ascitic fluid found on opening the abdomen; (2) the ovarian tumours followed the ordinary rule in being bilateral; (3) the right ovary was as large as any ordinary cystic adenoma of the ovary, papillomatous tumours as usually described being smaller; (4) there was no peritoneal infection, although the papillomatous growth had penetrated the wall of the right-sided tumour.

Dr. LLOYD ROBERTS commented on the absence of ascites and on the question of malignancy.

Dr. GEMMELL remarked on the frequency with which ovarian new growths and inflammatory conditions complicated fibroids of the uterus.

Dr. PERCIVAL BARBER (Sheffield) read notes of the following cases:—(1) Fibroma of the Abdominal Wall, which was removed from a woman, *æt.* 27. In the space of three months it had increased from the size of a small nut to a lump measuring 2½ by 1½ inches. It was situated about two fingers' breadth internal to the right anterior superior iliac spine. Removal was easy. (2) Ectopic Gestation. (3) Rupture of Uterus, which occurred in a very obese woman, *æt.* 32, who was sent into the Jessop Hospital after labour on account of a supposed rupture of the vaginal wall. Forceps having failed, the delivery had been effected by version. When Dr. Barber saw the patient she was comfortable, the temperature 102°, pulse-rate 126. Abdominal examination disclosed nothing unusual, the uterus being firmly contracted. Vaginal examination was difficult by reason of the patient's size, but no vaginal tear could be discovered. The cervix was ragged and a tag hung down from it. The urine contained a little blood at first, but none later. All day the condition remained good, but pneumonia developed at night. Next morning, after an action of the bowels, the patient became very ill and died in a few minutes, without exhibiting the classical signs of internal hæmorrhage. Autopsy on the same evening: Stomach and intestines greatly distended by gas; no evidence of peritonitis; the abdomen contained much free recent blood; blood was found also in both broad ligaments, chiefly in the right; a complete rupture of the uterus ran obliquely upwards from right to left, involving the lower uterine segment principally; Bandl's ring was very conspicuous.

#### THE SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

At a meeting held on November 18th, Mr. ROBERT JONES in the Chair, twenty-one new members were elected. The Glas-Sedilbanck lamp for the cure of lupus was demonstrated.

A specimen of "Congenital Atresia of the Tricuspid Valve" was shown by Dr. BERTRAM ROGERS (Bristol) and Dr. J. M. FORTESCUE-BRICKDALE (Bristol). The child, *æt.* 2, was admitted into the Children's Hospital, Bristol, suffering from bronchitis with extreme dyspnoea and cyanosis. The fingers and toes were clubbed, and the lips and extremities deep purple. There were no cardiac bruits and no apparent increase of cardiac dulness. She had suffered from repeated attacks of cyanosis. She died in a few hours. *Post-mortem*, the heart weighed 3½ oz. When opened it showed hypertrophy and dilatation, mostly of the right auricle and left ventricle, patent foramen ovale, atresia of the tricuspid orifice, and a small opening between the ventricles. There was no sign of endocarditis; the ductus arteriosus was closed.

A specimen of "Congenital Pulmonary Stenosis" was shown by Dr. GEORGE CARPENTER. The condition was associated with a perforated septum ventriculorum and a patent foramen ovale. The aorta in great part arose from the right ventricle. The heart was removed from a child, *æt.* 2, free from other congenital abnormalities. The right ventricle was hypertrophied and during life this was an obvious feature. There was a loud systolic murmur audible all over the pericardial area and of maximum intensity at the xiphoid; it was inaudible in the great vessels of the neck and only occasionally heard in the back. The lips were cyanosed, and the fingers and toes blue and clubbed. The child was born blue, and the cyanosis had latterly increased—she had twice been convulsed. The red corpuscles were 7,800,000 per cm., and the hæmoglobin 122 per cent. She died of measles. Dr. Carpenter drew attention to the large increase in the number of red corpuscles and of the hæmoglobin percentage, which in his experience was not an uncommon feature in cases of congenital morbus cordis with cyanosis. He also commented on the value of

the skiagram in such cases, and on the early advent of cyanosis. The absence of a systolic bruit in the great vessels of the neck was touched upon, and its value when audible there as a diagnostic sign of the condition of perforate septum ventriculorum was, he thought, of considerable importance.

A specimen of "Atresia of the Pulmonary Artery" was also shown by Dr. SYDNEY CURL.

A case of "Juvenile General Paralysis" was shown by Dr. JAMES TAYLOR. The patient was a boy, *æt.* 11½, the fifth in a family of nine, all said to be healthy. He was born at full term, suffered from abscesses "in the head and groin" at 1, but did not walk till he was 4. At 6 he developed a faculty for romancing, telling wonderful stories apparently merely to excite admiration. He was also frequently violent and vicious. The physical signs and the mental symptoms, slight as they may be, appear to indicate definitely that the case is one of juvenile general paralysis, and the physical and mental degeneration are likely to become much intensified.

A case of "Bell's Paralysis with a Hemiplegic Onset" was shown by Dr. J. PORTER PARKINSON. The boy, *æt.* 4, had been perfectly healthy till July last, when paralysis in the right arm and leg and left side of the face occurred suddenly. The weakness of the arm and leg passed away in a week, and, when examined, there remained only weakness of all the left side of the face. Dr. Parkinson thought the case due to a lesion of the nucleus of the facial nerve involving the pyramidal tract in some temporary manner, possibly passing oedema, and, from the sudden onset during the summer, with hyperæsthesia, in a previously healthy child, it resembled the lesion known as encephalitis inferior, pathologically similar to acute anterior polio-myelitis.

A case of "Ataxy of the Cerebellar Type" in a girl *æt.* 4, was shown by Dr. PORTER PARKINSON. The condition of the fundi of the eyes suggested it was a degeneration occurring in hereditary syphilis, though there was no other evidence, personal or family, to corroborate this.

A case of "Progressive Palsy" in a boy, *æt.* 13, was shown by Dr. HARRY CAMPBELL (introduced). The paralysis began in the legs at the age of five years, and was noticed in the hands at the age of nine, and in the face at the age of ten. It was symmetrical, and in the extremities mainly confined to the long extensors. Electrical reactions were normal. Dr. Campbell was uncertain as to the nature of the affection.

Three cases of "Unilateral Congenital Dislocation of the Hip" of varying degrees of severity were shown by Mr. DOUGLAS DREW.

A case of "Old-standing Dislocation forwards of the Head of the Radius," of two years' duration, was shown by Mr. DOUGLAS DREW. The dislocation was reduced by operation, but in spite of the greatest care the condition recurred. Inasmuch as the function of the arm was little impaired and the deformity was trifling, Mr. Drew advocated no further interference.

Two cases of "Cephalhæmatoma Neonatorum over the Occipital Bone" were shown by Mr. J. HOWELL EVANS, who subsequently gave a lantern demonstration on the subject. Mr. Evans considered these blood effusions were due to a reactionary hæmorrhage from a small artery which had been injured in the moulding of the infant's head during its passage through the birth-canal. Foetal skulls and many lantern slides of the skulls of various animals were shown to illustrate Mr. Evans' views. The author advocated the immediate surgical treatment of cephalhæmatoma neonatorum.

A case of "Graves' Disease" in a boy, *æt.* 12, was shown by Mr. SYDNEY STEPHENSON. The thyroid was enlarged, there was slight tachycardia, slight exophthalmos, and a curious pallid puffiness of each upper lid. There were no nervous symptoms.

Two cases of "Traumatic Keratitis following Difficult Instrumental Labour" were shown by Mr. SYDNEY STEPHENSON.

A specimen of a "Tuberculous Fallopiian Tube" and

"Tuberculous Ulcers of the Intestine," removed from a case of general tuberculosis, *æt.* 2½, was also shown by Dr. SYDNEY CURL. It was not suspected during life. The uterus and ovaries were healthy.

The cases were discussed by Mr. Robert Jones, Dr. Edmund Cantley, F. Parkes Weber, C. W. Chapman, G. A. Sutherland, C. O. Hawthorne and Mr. L. McGavin.

#### NORTH-EAST LONDON CLINICAL SOCIETY.

CLINICAL EVENING HELD THURSDAY, DECEMBER 1ST, 1904.

DR. R. MURRAY LESLIE, President, in the Chair.

DR. J. W. HUNT showed a middle-aged woman with an Innominate Aneurysm which had existed for two years without causing any deterioration of health.

The PRESIDENT exhibited (1) a case of Hæmo-Pneumothorax in a man, *æt.* 30, the origin of which was doubtful. The pneumothorax was limited to the upper part of the left chest. On aspiration of the base about half a pint of dark blood was withdrawn. The heart was considerably displaced towards the right, and there was a small band of hyper-resonance above the stomach due to a layer of compressed lung. The early symptoms presented by the patient were more abdominal than thoracic in character, resembling those of diaphragmatic pleurisy. All the ordinary causes of this affection could be excluded.

DR. HERBERT P. MILLER referred to a case which had been under his care in which the diagnosis of hæmo-pneumothorax was proved by the fact that paracentesis had been performed twice, and on each occasion blood was withdrawn. The patient made a complete recovery.

(2) A case of Actinomycosis in a man *æt.* 36 (through the courtesy of Dr. H. Cuff, Medical Superintendent of the North-Eastern Fever Hospital). The condition affected the left side of the face, inferior maxilla, and buccal mucous membrane. The typical ray-fungus was obtained microscopically.

MR. HERBERT CARSON emphasised the importance of giving very large doses of potassium iodide in such cases, and referred to the difficulty sometimes experienced in distinguishing actinomycosis from early cases of malignant disease.

MR. R. F. TOMLIN showed a case of Raynaud's disease in a middle-aged woman.

DR. J. A. WHITING showed an in-patient at the Tottenham Hospital, the subject of an Aneurysm of the Ascending Aorta. The patient was a man, *æt.* 48, and the aneurysm was visible externally as a tumour the size of a goose's egg, situated to the right of the upper end of the sternum.

The PRESIDENT remarked that the sac was probably well-filled with clot, as a murmur could only be faintly heard over it. He considered that the case was a suitable one for attempting a cure by the introduction of silver wire.

MR. WALTER EDMUNDS thought that surgical interference was for the most part impracticable in aneurysms of the aorta, but in the case of innominate aneurysm exhibited the effect of the distal ligature might be well worth considering. The treatment of gelatine injection was sometimes open to fallacy, as the improvements reported after its use might conceivably be due to the enforced rest in bed to which the patients had to submit. Mr. Edmunds also exhibited (1) a boy, *æt.* 13, upon whom he had operated for Ruptured Liver. A collection of bile had re-formed shortly after the operation. There was very little hæmorrhage.

DR. WHITING asked whether this case might not have been an example of the condition known as "bile-cysts," and referred to a case reported by Mr. Alban Doran, in which operation was performed three years after an injury to the right hypochondrium.

(2) A boy, *æt.* 12, from whom he had excised a growth of the inner end of the left clavicle. The appearances

at the time of the operation suggested an endosteal sarcoma.

DR. DAVID McASKIE showed a case of Splenomegaly Leukæmia in a man, *æt.* 38. He had been treated with arsenic for seven weeks, but subsequently he had had the X-rays applied twice a week. Before the latter treatment was commenced the blood-count was as follows:—red cells, 3,000,000; white cells, 392,000. Three weeks afterwards the leucocytes had diminished to 40,000, and the spleen was lessened in size to the extent of two inches. Of late a little perisplenitis had developed. The large mono-nucleated leucocyte predominated.

MR. CARSON showed a Cyst of the Tongue which he had removed from the case exhibited at the last meeting of the Society by Dr. F. Tresilian, and which proved to be a sequestration-dermoid, there being no connection with the thyroglossal duct.

DR. ARTHUR E. GILES exhibited a specimen of an Ossified Fibro-myoma Uteri. The patient was a woman *æt.* 65, in whom a hard tumour could be felt present at the external os. The capsule around it was sloughing, giving rise to a most offensive vaginal discharge. In spite of the narrowness of the vagina, it was decided to attempt the removal of the mass by that route. The operation was attended by no small difficulties on account of the hardness of the tumour and the constriction of the natural passages. The fibroid was ultimately extracted after splitting the cervix and parts of the posterior vaginal wall, and rotating the tumour upon its long axis. The mass weighed 15 oz. The patient made a good recovery.

#### THERAPEUTICAL SOCIETY.

MEETING HELD NOVEMBER 22ND, 1904.

SIR LAUDER BRUNTON, President, in the Chair.

THE SECRETARY read a paper by Dr. GORDON SHARP of Leeds, who was unable to attend, on  
STRYCHNOS TOXIGERA AND OTHER PARALYSERS OF MOTOR NERVE ENDINGS.

He said many had endeavoured in vain to discover the plant that produced curarine, until Mr. J. Quelch brought him, in 1902, some poisoned arrows and specimens of the plant given him by an Indian chief of Guiana. The plant was found by Mr. E. Holman to be the *Strychnos toxigera* (Benth), and curarine was found in the bark, but not in the leaves. This alkaloid is very deliquescent and easily decomposed—its salts are more stable; commercial curarine contains 9 to 11 per cent. of the alkaloid. Curare has been used in chorea convulsions, and to prevent painful spasms in moving wounded persons. He compared its action with that of strychnine, delpho-curarine, alstonine, aconite, snake-poison, and diphtheria toxin.

The PRESIDENT said that the paper reminded him of one by Majendi, on the upas poison, which was *strychnos nux vomica*. He thought alstonine might be useful in cases of excessive itching in diabetes and albuminuria.

DR. CRICHTON remarked that death from curare in frogs occurred only after forty hours, while strychnine killed them in two hours.

MR. G. C. MOOR, F.I.C., F.C.S., read a paper, entitled  
NOTES ON BRANDY,

showing that the different constituents in brandy could be accurately estimated by chemical analysis, but it was quite possible to prepare a brandy which would answer every analytical standard and yet not be brandy as understood and prescribed by the medical profession. Therefore brandy factories should be properly inspected by Government, as is done in Australia with the Orion brandy exported to this country.

SIR LAUDER BRUNTON remarked that the effects of wines were very diversified. Some promoted merriment, others quarrelsomeness, but it was impossible to say on what this depended, and the same results probably followed on the imbibition of various brandies, whether pure or adulterated.

Mr. McEwen said that nine-tenths of the brandies met with were not really brandy at all, but a mixture. Ether could easily be added to silent spirit and form a good imitation.

### TREATMENT OF DYSMENORRHOEA.

EVERY practitioner knows how painful and troublesome dysmenorrhœa is, and the following counsel given by M. Dalché on the affection may be useful.

The first thing to be done is to discover the cause of the malady. Constipation should be avoided as well as intellectual and physical fatigue. To ease the pain, simple means may be at first enjoined—rest, warm applications, belladonna suppositories. An enema may be given in the morning with:—

Antipyrine, 15 grs.;  
Laudanum, 20 drops;

or the following ointment:—

Extract of hyoscyamus,  $\frac{1}{2}$  dr.;  
Extract of belladonna,  $\frac{1}{2}$  dr.;  
Vaseline, 1 oz.

As to applications of ice, recommended by some, they are dangerous, for if they ease the pain they may arrest the flow of blood. A German author, Fliess, having found that there existed regions of the mucous membrane of the nasal fossæ constituted of erectile tissue, remarked that when the ovary became turgescient the mucous membrane of the nose was similarly affected. Hence he wanted to endeavour to calm the pain of dysmenorrhœa by touching the nasal cartilage with a solution of cocaine and with some success.

M. Dalché tried the method of Fliess with satisfactory results in some cases.

When the blood is normal in quantity at each period, antipyrine should be prescribed in 15 gr. doses, associated with 10 grs. of bicarbonate of soda, or 6 grs. of pyramidon. Dr. Huchard recommends:—

Tincture of piscidia erythrina, 10 grs.;  
Tincture of viburnum prunifolium, 10 grs.

Twenty drops four or five times daily.

For lumbar neuralgia, ichthyol externally is very efficient.

Ichthyol, 2 dr.;  
Chloroform, 3 dr.;  
Camphorated spirits, 2 oz.

Between the periods cannabis indica should be prescribed.

If the flow was excessive (menorrhagia), the fluid extract of hydrastis canadensis is indicated (20 drops three times a day). If, on the contrary, the flow is insufficient or slow to appear, general tonic treatment should be ordered with ovarian opotherapy.

Where the menses are entirely irregular, cold bathing, corporal exercise, gymnastics, and ovarian opotherapy will render good service. Marriage might also be recommended.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 4th, 1904.

At the Society for innere Medizin, Hr. Hirschfeld discussed

### THE PROGNOSIS OF DIABETES.

He said that in general diabetes was divided prognostically into two groups—into the grave, which was distinguished by the appearance of sugar in the urine even where no carbohydrates were given in the food, and into the mild, in which this was not the case. The grave form ended fatally within five years; the mild, on the other hand, with favourable conditions of life, and with suitable feeding, &c., led to no great shortening of life. This view had been given expression to by Naunyn, and it had been generally agreed to. According to the speaker, this was not correct;

according to his observations a portion of these milder cases died during the first ten years of the disease. The cases of the mild group were not all alike; the amount of sugar was of great importance; the urine should be examined for months, in order to ascertain how much carbohydrates could be digested. According to this the speaker divided this group again into two groups: First, the cases that from 100 grammes of carbohydrates excreted 20 to 25 grammes of sugar, and second, those that from the same quantity excreted 10. In the first group nephritis came on between the 4th and 7th years, and between the 40th and 55th year of life. Polyuria, adiposity, nephrolithiasis and cystitis all appeared to favour the development of nephritis. The nature of the nephritis was not yet clear. The speaker thought it was a chronic parenchymatous nephritis and not one from arterio-sclerosis. As regarded diet, he rejected milk, but recommended cream, and a diminution of the quantity of flesh. Outside of nephritis the causes of death in the middle group were coma, apoplexy, cardiac weakness, and, rarely, gangrene and tuberculosis. Few of these cases died of intercurrent diseases.

At the Gesellschaft der Charites-Aerzte, Herren Mossen and Milchner spoke on the

### TREATMENT OF BLOOD DISEASES BY THE RÖNTGEN RAYS.

The X-rays destroyed the follicles in the spleen and the lymphatic glands just as in the medulla of bones, as experiments on animals had proved. The white cells were influenced whilst the cells containing hæmoglobin were resistant. In so far the X-rays exercised an electric action. This discovery was opposed to the assumption that both sets of cells were from a common stock. Eczema or injury to the roots of the hair was never observed in the animal experiments. Preparations of blood and bone marrow were shown.

Hr. Krause had seen failure in a case of mixed-celled leucæmia. Hr. Gorawitz observed that all erythroblasts did not originate out of a white preliminary stage; most were found by homoplastic increase. In a case of leucæmia he saw a surprising result from the X-rays.

Hr. Kaiserling observed that after the destruction of the follicles mentioned there was a remarkable regeneration.

Hr. Senator had seen marked diminution of the spleen in three cases after application of the rays.

VIENNA, December 3rd, 1904.

### GAS CYSTS IN THE BRAIN.

At the Prague meeting, Chiari raised a discussion on multiple spaces in the substance of the human brain, without any lining or covering to indicate a cavity produced by fluid. Clarke gave it the name of the Swiss cheese brain, from its appearance to that article of diet. Reuling and Herring, in 1899, came to the conclusion, after many experiments, that the cavities were formed by the accumulation of gas produced by the bacillus aerogenes. Since that time, many interesting cases have been published, while the brain substance has been preserved by hardening with formol, and sections thereafter made to demonstrate the lamellæ of the cyst. Chiari reported five cases that he had seen himself since 1893, two from typhoid, one from Bright's disease, and two from sephthæmia or septicæmia. These cysts were demonstrated on *post-mortem* and after hardening. In one of the sephthæmia cases large emphysematous cavities were found in the subcutaneous, intermuscular, mediastinal, and sub-peritoneal cellular tissue, as well as the presence of typanites uteri. The streptococci pyogenes of puerperal females produce the same results as those of the *aerogenes capsulatus reni*, which have been cultivated

In a brain suffering from the latter, one-half was cut into sections, but no cysts could be observed; the other half was hardened in formol, with the result that after two months beautifully laminated cysts could be found with the corresponding bacteria. This was also the case in one of the sephthæmia cases.

#### EHRLICH'S COLOUR REACTION.

The red colour of urine with a salt of dinnethyl-amin-benzol-aldehyde (Ehrlich) depends upon the presence of urobilin or its derivatives. Although this may not be pathognomonic, it indicates the presence of pyrrol, which, according to Nencki and Zaleski, forms the colouring matter of the tissues. Its pathology in the urine is to be found in cases of pneumonia, blood diseases, and hepatic disorders in which the reaction is very much accentuated from the normal conditions. The absence of this reaction in the urine is to be found in cases of icterus, where the choledochus and hepaticus is closed. The gall secretion gives a red colouring with the aldehyde, because it contains the urobilinogen. This aldehyde reaction is also found in the fæces, where indol, skatol and urobilinogen are present. Hæmopyrrol, which is found in all blood colouring matter, and is therefore present in most of the albuminous secretions of the body, with the exception of gelatine or gluten is too comprehensive to be of any real value in the diagnosis of any individual disease, although Ehrlich himself contends that there are various shades of colours produced with concentrated sulphuric acid that give a violet colour when the indol group is present with a molecule of albumin. The aldehyde may be considered a reagent for all the pyrrol derivatives. The red colouring is not confined to the acid form, as acetyl-glycos-amin, when treated with an alkali, and the aldehyde produces the red colour also.

#### ALKAPTONURIA.

Falta treated the audience to a long history of a case of alkaptouria, which is the morbid elimination in the urine of a uroleucin salt, sometimes designated hæmogenitisin. This substance is often present in healthy children as well as in cases of diabetes and phthisis, and can be detected by Fehling's solution. It would seem from Falta's observation that hæmogenitisin is obtained in small quantities from albuminous bodies, and may be recognised as an amino-complex salt and eliminated in a form of alkaptouria. The administration of bromine and iodine checks the elimination in the urine by their action on the albuminoid molecule. It is therefore a specific change when this hæmogenitisin is produced, as the whole disturbance is located in the structure of the albuminoid molecule. Langstein said that he always considered hæmogenitisin to be closely allied to tyrosin, which he had obtained from plants as an experiment with phenylalanin with sections of turnips, whose ferment will produce the so-called hæmogenitisin salt. Klemperer asked if there had been any hereditary conditions to cause alkaptouria in Falta's cases, as consanguinity was often found to be present in these cases. Falta said that neither consanguinity or hereditary could be proved.

#### HIS AND WEIGERT.

The journals this week contain long records of the scientific work of these two investigators. His was known in anatomy and embryology, and his works have now become classic. Born in Basle, 1831, he studied under Müller, and Remak, and became professor of anatomy in his own university in 1857. Weigert died rather suddenly in his fifty-sixth year. His investigations lay in the examination of the secretions and blood circulation according to Cohnheim's views, and he finally devoted the whole of his time to bacteriology and histology in conjunction with Koch and others. His methods of colouring sections will long be remembered by students of medicine.

## The Operating Theatres.

### ROYAL FREE HOSPITAL.

OPERATION FOR TRAUMATIC EXTRA-DURAL HÆMORRHAGE.—Mr. T. P. LEGG operated on a man, æt. 35,

who had fallen on to his head whilst riding a bicycle. He was unconscious for a moment, but recovered quickly and rode on home, a distance of about half a mile. He went to bed at once and complained of a good deal of headache, especially in the frontal region. There was considerable epistaxis, and the left eye was proptosed. He was sick once or twice, and remained unconscious for some hours; then he became quite unconscious about twelve hours after the accident. On admission, he could not be roused, his breathing was not stertorous, his pulse was 54, full and regular. The pupils reacted very slightly to the strong light, the left pupil being somewhat larger than the right. There was a superficial excoriation over the left eyebrow, and a large hæmatoma around it extending into the eyelids of the same side. On separating the left eyelids an extensive sub-conjunctival hæmorrhage was found on the outer side of the globe of the eye. The right arm and leg were paralysed, and dropped when raised more quickly than the left arm and leg; both knee-jerks were present. There were no other injuries. A diagnosis of fissured fracture extending into the base of the skull through the anterior fossa, leading to extra-dural hæmorrhage, was made and immediate operation undertaken. A large flap consisting of the whole of the structures of the scalp was turned down from the temporal and frontal regions of the left side; the fissured fracture was then seen running vertically downwards in the frontal bone a short distance behind the external angular process, and one or two small fissures radiating from the main one. A 1-inch trephine was then used to remove the bone close to the main fissure; a large clot was at once exposed. The opening in the skull was rapidly enlarged by Hoffman's forceps and the clot removed by means of a Volkman's spoon. On the dura mater a small branch of the middle meningeal artery was found to be bleeding, and this was tied by running a suture underneath it. The clot extended downwards into the anterior fossa of the skull, and about four ounces of it were removed. The dura mater was seen to be pressed inwards so as to form a saucer-shaped depression; the brain could be felt pulsating as soon as the clot was removed; it at once began to expand as soon as the pressure of the clot on it was relieved, and the depression in the dura mater for the most part then became obliterated. Running across the anterior fossa, a fissured fracture was found passing from left to right, and somewhat backwards. The bone was not replaced, and two or three small pieces of gauze were placed in the space between the dura mater and the bone. The flap was sutured in position, a drainage-tube being inserted through a counter-opening in the middle of its base, the pieces of gauze being brought out at each end of the incision. Mr. Legg said that this was a typical case of extra-dural hæmorrhage, showing all the classical symptoms, namely, an injury and temporary loss of consciousness, recovery of consciousness, and then steadily increasing coma. The signs present were very characteristic, a slow pulse, which was of good volume and regular; the condition of the pupils and a hæmatoma of the scalp suggested the seat of the fracture and the place where any operation should be performed. The projection of the left eye was due to hæmorrhage behind it, and this, coupled with the epistaxis, suggested what was found to be a fact, that there was also a fracture of the base in the anterior fossa. As regards the operation,

a small amount of chloroform was required while the skin incision was being made; afterwards the operation was completed without any more anæsthetic. When the clot was exposed no pulsation was observed, which suggested that the hæmorrhage had naturally ceased, and when the clot was removed no recurrence of the bleeding took place, so that the actual source of the blood was not defined. The small vessel which was ligatured on the surface of the dura mater was unlikely to have been the source of so large a hæmorrhage, which, it was probable, came from a sinus at the base of the skull, and in order to prevent its re-accumulation, if any subsequent hæmorrhage took place, the gauze drains were placed inside the cavity. The bone was not replaced because the brain had not completely expanded, and, therefore, the pieces of bone might have become displaced and acted subsequently as a source of irritation. As regards the prognosis in these cases, it must be always grave. A certain number of patients do recover, but the majority, even when the hæmorrhage is capable of being dealt with and diagnosed as in this case, will die for these reasons: First, extensive injury to the brain itself leading to subdural hæmorrhage; second, the pressure to which the brain is subjected, and which prevents the brain expanding when the clot is removed: if this expansion fails to take place the patient invariably dies; and, thirdly, other injuries, as extensive fracture of the base of the skull.

The patient recovered consciousness five hours after the operation, and recognised that he was in the hospital. His pulse was 72 per minute, and otherwise normal; the right pupil reacted readily to light, and was normal in size. He subsequently made an absolutely uninterrupted recovery, and left the hospital in the fourth week after operation.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 7, 1904.

### INFANTS' HEALTH SOCIETY.

INFANTILE mortality is one of the chief socio-hygienic problems of the day. No single question is more worthy of study, for in the infantile death-rate are reflected all, or nearly all, the diseases of corporate national life. The extent to which infant mortality prevails expresses the sum of the

factors of intemperance, over-crowding, insanitary conditions, improper and insufficient food, parental neglect, and want of education. All these the infantile death-rate denotes, but it connotes more—namely, the measure in which the brothers and sisters of the dead children are being affected in mind, body, and estate by the same conditions. To medical men the influence on the rising generation of these conditions is, and has been for many years, painfully apparent, but for the most part their warnings, born of experience, have fallen on deaf ears. We are glad to note that now, before it is too late, these warnings are beginning to be heeded, and that in the "physical degeneration" scare which followed the South African War the facts brought to light have stirred a desire and a determination on the part of many influential and philanthropic people to tackle the problem in earnest. In the columns of the *Times* a series of bold, strongly-worded articles has been appearing dealing with the matter in various aspects, and the recent foundation of the Childhood Society and the Infants' Health Society, both of which include laymen as well as medical men among their members, also points to an amount of interest in the welfare of the young of poor parents that is very gratifying. It seems likely, then, that in the near future definite and concerted action will be taken to reduce by every practicable means a mortality and sickness amongst the infants of this country which may be characterised as a blot upon our civilisation. The matter, however, is not a simple one; it involves in reality the rectification of practically every social disadvantage and sanitary disability existing—a task that might well cause the stoutest heart to quail. The first and foremost necessity is for all engaged in the task to be well cognisant of the nature and extent and causes of the evil, and be thoroughly clear and unanimous as to the right line of procedure. Enthusiasm is good, but enthusiasm must be tempered with discretion. The Infants' Health Society, which was formed in February of this year, has placed before itself an ambitious task, and actuated as it is by an ardent desire to save the lives and improve the physique of the children of the poor we need hardly say that we are in entire sympathy with its main aims. This sympathy, however, must not deter us from offering a few friendly criticisms of the methods by which it proposes to work and the means which it proposes to adopt to attain its ends. The society has published a pamphlet setting these forth, and this pamphlet is now available for distribution to those likely to be influenced by it. It is to be regretted that the writer of this pamphlet in urging a good cause has allowed himself to be betrayed into hyperbole, and that instead of setting forth the sober facts—which are convincing enough in all conscience—he has allowed his pen to run into a certain extravagance. For instance, such a statement as that "among substitute-fed infants, it is becoming a comparatively rare thing to find a single case of healthy growth and development," is not likely to find endorsement in the experience

of those into whose hands the pamphlet falls. The bulk of town-bred children are wholly or partially substitute-fed, and fortunately there are still a good many healthy among them. Sweeping generalisations of this kind, and there are several similar ones, tend to endanger an excellent cause; good wine needs no bush. The society rightly insists on proper feeding in infancy playing a leading part in the avoidance of death and disease, and insists also on the undesirability of undermining parental responsibility in the up-bringing of children. It is true that great difficulty is experienced by employed women in nursing their children at the breast; but the importance of doing so whenever possible should be recognised fully by all enlightened endeavour. The question is largely one of education—the tradition of breast-feeding is dying out in many classes owing to a great extent to the cheapness of tinned milks and the fashion of babies' foods. These two points, the education of the mother and the encouragement of breast-feeding, are the greatest desiderata. Too much stress, we think, is laid by the society on the provision of milk depôts for the distribution of milk—free or for small payments. In the first place the cost of an organised system of depôts all over the great towns, such as they wish to institute, would be enormous, and in the second, it would militate against the principle of parental responsibility. The society would do well to direct their most strenuous efforts towards the reformation of the milk trade, so that the poorest could be assured of obtaining a perfectly trustworthy article of diet for their young. The modification of cow's milk to suit the human infant is not such a difficult matter as the society seems to think; it can be done easily by anyone if properly instructed, and the best way to aid in this particular is to urge local authorities to appoint female health visitors to educate and help ignorant mothers. The potentiality for good of such visitors is enormous, both in bringing to light parental neglect and in teaching those willing to learn, provided suitable women are chosen for the posts. We think that the society would be more likely to be successful if they worked on these lines than by embarking on a policy so expensive and difficult to maintain as that of the wholesale provision of milk depôts.

#### MICRO-ORGANISMS IN THE STOMACH.

It has long been recognised that an important function of the hydrochloric acid in the gastric juice is the destruction of bacteria ingested with the food. With every mouthful of food, particularly raw foods and cold meats, we swallow myriads of living organisms, yet it is probable that as long as a stomach is healthy but few of them pass the pylorus alive. On the other hand, any departure from health, such as ulceration, diminishes considerably the bactericidal power of the gastric juice or gives organisms such a firm foothold that its action is neutralised. Some observations and experiments recently made by Dr. Hewetson, of

Birmingham, (a) illustrate this in a conclusive manner. In a number of patients suffering from gastric dilatation, the opportunity of a gastro-jejunostomy was taken to obtain specimens of the gastric contents for bacterioscopic examination direct from the stomach. In 83 per cent. of the cases where there was no ulceration the stomach was sterile, while in only 28 per cent. of those with ulceration was it so. Dr. Hewetson has also, by experiments on himself and a number of gastrostomy patients, discovered the approximate time required by a healthy stomach to destroy certain classes of bacteria. He found that rich growths of staphylococcus pyogenes aureus were completely destroyed in from thirty to forty-five minutes after being swallowed, while bacillus pyocyaneus required about twice that time. Further, it is noted that no ill result ever followed the ingestion of virulent cultures of these organisms. The practical bearings of these observations are wide, both in the domains of medicine and surgery. On the one hand they show us of what importance it is in the prevention of intestinal infection that the gastric wall and its secretion should be in a healthy condition. Though, of course, it is impossible to perform experiments with the typhoid bacillus similar to those reported by Dr. Hewetson, there is no reason to believe that its resistance to gastric juice is greater than that of the organisms with which he has experimented. If we are right in this, it will tally with the current belief of clinical observers that a low state of vitality generally, and particularly a disorder of the gastric secreting function, is an important element in the causation of that disease. From the surgical point of view, the comparative sterility of the stomach and jejunum is of interest as showing how slight is the danger of sepsis in most cases of operation on these viscera, and as explaining the ease with which small wounds, such as bullet wounds, of the upper part of the alimentary canal heal. From bacterioscopic examination of the extravasated fluid in cases of perforation of the stomach, important practical results follow as regards prognosis. If the fluid should be, as often happens, sterile, an excellent prognosis may be given. On the other hand, though the presence of bacteria does not necessarily mean a bad outlook, yet the prospects are worse in proportion to the number and virulence of organisms present.

#### MEDICAL MEN AND POISONOUS DRUGS.

LAST week the City Coroner, Dr. F. J. Waldo, held an inquest which opens up many considerations of importance to the medical profession. The inquiry was held by him upon the body of a man whose death was alleged to have taken place from an overdose of opium prior to his removal for an operation at St. Bartholomew's Hospital. The facts of the case, briefly narrated, were as follow. For several weeks deceased had been ailing, when he became so much worse that his

(a) *Brit. Med. Journ.*, November 26th, 1904.

medical man called in a consultant. The latter diagnosed appendicitis and ordered opium externally and internally. A box of pills was sent with the directions that one pill was to be taken every four hours, instructions which were followed by the nurse subsequently engaged, although she stated that she had no knowledge of the nature of the medicine. She had then seen neither of the medical men in attendance, and when she left the case for purposes of rest she gave the patient's mother instructions in writing to continue the pills. The mother and three other witnesses swore that both boxes had written instructions upon them to the effect that two pills were to be given every half hour until sleep was induced. The medical attendant, on the other hand, swore that there were no written directions at all on the second box but that he had ordered two pills to be given at once, and one pill every two hours afterwards until sleep followed. The nurse's version of this was that he directed her verbally to give two pills at once and two more every half hour subsequently. The attention of the medical attendant was at length arrested by the state of the patient's eyes, and he himself admitted in evidence that he remarked that the sick man "had had too many pills." A surgeon was summoned who advised immediate operation, which was performed at St. Bartholomew's Hospital on the Saturday evening, but the patient died on the following evening. Under these circumstances it is hardly to be wondered that the relatives of deceased communicated with the Coroner. There can be little doubt that owing to some misunderstanding an unusual amount of opium was administered to the patient. According to the wife's statement, she gave her husband twenty or thirty pills between 11.30 a.m. and 4 p.m. on the Saturday. The surgeon stated that death resulted from shock and not from the effects of opium. A *post-mortem* examination revealed extensive organic disease, so much so that it was extremely improbable deceased could have survived any severe operation. That fact, however, does not shift the responsibility for the laxity shown in dealing with so dangerous a drug as opium. Clearly it would be inadvisable for medical men to label distinctively all medicines for internal use which happen to contain poison. At the same time ordinary prudence would suggest that in giving opium pills no more than a maximum day's dose should be entrusted to the patient's friends, and that clear and full written instructions should be appended. Had a chemist dispensed boxes of opium pills in the wholesale fashion that appears to have been done in this case, especially without proper directions, or with none at all, as the medical man asserted was the case with the second box, he would have laid himself open to a charge of manslaughter. Speaking generally of another aspect of the case the use of opium in latter days has considerably diminished, in fact, many modern practitioners would regard opium as a last resort in hopeless cases and would then order it only

with the merciful view of securing a state of euthanasia. The use of narcotics in appendicitis has been practically abandoned and there appears to be little question that its administration merely serves to mask symptoms and greatly to reduce the chances of success in any operative measures that may be afterwards undertaken. However, opium no doubt still has its value in skilful hands, and under special circumstances which were no doubt present in the case under notice. On the whole the medical attendant may consider himself somewhat fortunate that he has escaped more serious consequences than a rider from the jury, representing that in all cases where medical men prescribed poisons it was desirable that the package should bear instructions as to their administration but not necessarily the name of the drugs. Had this particular inquest been in the hands of a pathologist and a coroner whose relations with the medical profession were not of the most cordial nature, the results might have been of a less reserved and conciliatory character.

## Notes on Current Topics.

### Mr. Beck's Double.

AN interesting example of the ethics of irregular practice is supplied by the history of John Smith, the criminal who, in addition to his original misdemeanours, allowed another man to suffer the punishment that should justly have been his. John Smith who, after all, is not particularly like the unfortunate Mr. Beck in appearance, has passed a wandering, adventurous life, living apparently for the most part "on his wits," and in certain stages of it not doing so badly. He is said to be a man of extraordinary ability and intelligence, who can speak and write no fewer than thirteen languages and was at one time the moving spirit of all gatherings and social functions in Adelaide. He has been in many countries and is possessed of a large amount of general information about people and things, not the least interesting of his experiences being those gained in the Hawaiian Islands as assistant to Father Damien in ministering to the lepers. But the part of his career which will have most interest to medical men is that spent in Australia, where he set himself forth as a specialist in the treatment of tuberculosis and skin diseases. Where he gained his knowledge is somewhat of a mystery, but when he was challenged as to his right to practice, diplomas of high merit were forthcoming to substantiate his claims. To whom these diplomas were originally granted is not known, but Smith made a great reputation on the strength of reputed medical knowledge and skill, and gained a large and lucrative practice; so much so that the general practitioners of Adelaide found his opposition cut seriously into their incomes. His practice is said to have been the largest in the town, and even legally-qualified practitioners seem to have availed themselves of his help from time to

time. Why he gave up a comfortable livelihood is not mentioned, but probably the routine of medical work preyed on his versatile nerves, and he set off on some more exciting pursuit. The moral of the tale is so obvious that one need not dwell on it; the spirit of the irregular practitioner is essentially that of the adventurer, and from quackery to crime is but a short step.

#### Alcoholic Automatism.

It is not an uncommon occurrence that certain acts are committed by a drunken person of which, when sober, he is quite oblivious. Indeed, after a violent fit of intoxication, more often than not the subject forgets a great part of what happened while he was in that state. Of entirely different order, however, and deserving of close study, are those cases of temporary loss of consciousness which sometimes occur in habitual alcoholics. It happens that a patient in this condition may commit some offence against the law, for which he is afterwards brought to book, although he protests, quite truly, entire ignorance both of the alleged crime and of his own movements at the time. Dr. Crothers, the distinguished American alienist, deserves credit for drawing the attention of medical men to this condition, which indeed is often unrecognised. It usually occurs in persons who are in the habit of consuming fair quantities of spirits, without at any time actually becoming drunk. Suddenly, and for a period varying from some hours to several days or even weeks, the patient passes into a condition of unconscious automatism, exactly resembling that which may occur in epileptics following a fit. On recovery from the condition his mind is an entire blank as to what has taken place during the interval. His actions may have been perfectly regular and usual, attracting no attention from those he has met. On the other hand, he may, apparently in a sober and rational manner, have performed some strange act, such as murder, wrecking a train, or disposing of his property without cause. Without going into the vexed question of the degree of criminal responsibility in alcoholics, it is obvious that it is the duty of physicians, as well from a scientific as from a medico-legal point of view, to study carefully any cases of alleged amnesia which occur in alcoholic subjects.

#### Osteopathy in England.

THE "science" of osteopathy is largely cultivated in America; it has its colleges, its professors, its diplomas, and its *clientele* of laymen, who prefer the ministrations of the osteopathic doctor in times of sickness to those of the legitimate practitioner. Not the least use to which the Americans put their boasted freedom is that of choosing what "system" their ailments shall be treated by, and as their proverbial "cuteness" is allied with a generous share of credulity the quack of all species has an excellent field for his enterprises. The osteopathist is quite a recognised institution in many States, and Bills have been introduced into their legislatures to legalise his position as a

practitioner. Fortunately these Bills have all been defeated, and, more fortunately still, the osteopathist has not hitherto ventured to cross the Atlantic. But whether it be from the local over-production of osteopathists or from the science developing cosmopolitan tendencies, this country is at present to have at least one professor dumped into its midst. His arrival has been heralded in the columns of one of the small fry of "society" journals who keep up their circulation by providing mild sensations for their readers. This particular publication is somewhat partial to novelties in the medical line, so that the osteopathist is quite a little god-send to it. Some time back its columns were descanting on the skill of an appendicitis-curer who was able to accomplish by electricity all that surgeons could or could not do for that disease by the knife. This professor seems to have disappeared, for we have not heard of him lately, but his place is more than supplied by the osteopathist who can remove stoppages in the blood, "merely in a moment," and by replacing bones and untwisting muscles is able to perform "some instantaneous cures." We only regret that there is no instantaneous cure for those who are beguiled by such nonsense.

#### Abolition of Sea Burial.

A PROPOSITION of a curious sort is being mooted at present in New York. It is that a law should be passed forbidding the burial of any dead body at sea. We confess, on first reading the suggestion, we were in some doubt as to how it could have originated, but the matter afterwards became clearer. The custom itself is an eminently sanitary one, and it seemed hard to find any arguments against it. On the other hand, the retention of a body till land could be reached is open to grave objection. In but few vessels would there be any sufficient method of preservation available, and the keeping a dead and decomposing body for weeks on a tropical voyage would be no less offensive than dangerous. Indeed, in many cases it would be an impossibility, and in all an inconvenience. The explanation of the suggestion, however, is simple. It originated in an address given by the President of the New York State Embalmers' Association! We shall hear next probably of gravediggers demanding a law to put a stop to cremation.

#### The Antiseptic Barber.

DR. COLLINGRIDGE'S recommendations for safeguarding the City populace from infection conveyed at hairdressing establishments have been approved by the Court of Common Council, and have now been published. They are certainly thorough, and if carried out by the barbers with the same zeal as that with which they were conceived by Dr. Collingridge, a "shave and hair-cut" in the heart of the Empire should have no terrors, even to the most timorous. The regulations demand that all shelves and fittings in hairdressers' shops small be made of glass, marble, or other impervious material; that clean towels be used and fresh

paper or linen placed on the head rest of the chair for each customer; no sponges or powder puffs be used; all shaving-brushes, combs, scissors, razors, &c., be placed in disinfectant solution after use; no general alum-blocks be used as a styptic; and various other drastic measures for ensuring cleanliness be instituted. Hairdressers complying with these demands will be registered and certificated as fit and proper persons to undertake the removal of superfluous hair from their clients. We should be inclined to regard the scheme as Utopian were it not for the fact that the regulations were drawn up and approved by a joint committee of the Public Health Committee of the Council and of the Incorporated Guild of Hairdressers, and it may be taken as certain that the latter would not have sanctioned any measures that could not be carried out in consonance with business principles. There are, however, many small barbers' shops at which the penny and three-halfpenny shave is a great attraction, and we confess ourselves unable to see how such establishments are to carry on their trade at a profit unless their prices are raised materially. At any rate, the ideal of what a barber's establishment should be and how it should be managed will be lifted to a higher plane by the action of the Common Council, and we trust their excellent example will have an influence extending far beyond the square mile over which they rule.

#### Surgery in the Newspapers.

OUR readers are aware that some of the less reputable of the London daily papers have been in the habit during the past year or two of publishing paragraphs dealing in a sensational manner with surgical affairs. The articles are usually ill-informed, and almost invariably give the public a false impression of the matters dealt with. In addition they not infrequently give an unseemly prominence to the name either of some hospital, or still worse, of some surgeon. We regret that this custom, which we had hoped was confined to the London press, is spreading to other places, and within the past week two respectable Dublin newspapers published paragraphs of this kind. In one case a highly-coloured and absurdly inaccurate account was printed of the operation for excision of the Gasserian ganglion which had been done a day or two before in one of the Dublin hospitals, the name of the latter being given. Among other things it was stated that this was only the fourth time the operation had been performed. In the other case a long account was published of an operation on the stomach for the removal of foreign bodies. It is greatly to be regretted that respectable journals lend themselves to the purveyance of sensational news of this sort.

#### A Consumption Cure.

AN amusing action was tried before Mr. Justice Lawrence last week in which a Mrs. Long sued Dr. Boyd for breach of contract in connection with the discovery of a treatment for consumption which Mrs. Long was trying to introduce to the notice

of the world. The remedy in question is a blending of herbs which is described as an "absolute cure," and a good deal of fun was created in the course of the trial by one of the witnesses relating that her husband had died of consumption after taking this absolute cure. The plaintiff conducted her own case, and the evidence produced in support of it was so slight that the jury returned a verdict for Dr. Boyd without leaving the box. Indeed, no other result was possible, and so ridiculous were the proceedings that Dr. Boyd is more to be condoled with on the annoyance and expense to which he was subjected than congratulated on a result which was inevitable from the beginning. One of Mrs. Long's witnesses was Sir William Broadbent, who confessed that he had no idea why he had been subpoenaed, and whose evidence consisted principally in shaking his head when asked several times if he would not try her remedy on hospital patients. The Judge excused him from attendance as soon as possible, and the farcical action continued. A man named Smith who had been given up as an incurable consumptive gave evidence that he had been cured by Mrs. Long, and that his case was a most complicated one. Dr. Watson, who was called by Dr. Boyd, was able to prove that the complications from which Smith suffered did not include consumption, and altogether Mrs. Long's patients did not provide very good advertisement for the absolute cure. The ground for the action was professedly that Dr. Boyd had availed himself in confidence of the precious secret and exploited it for his own profit—an insinuation one would have thought that hardly needed rebutting. It is a curious thing that the time of the courts can be wasted, and professional men put to inconvenience and expense, for silly actions of this kind; the only function they serve is to entertain the readers of evening papers. The doctor as a rule has to make sufficient appearances in court as a witness without being summoned in frivolous action, which are of no use to anybody except the lawyers.

#### The Treatment of Bad Temper.

WE do not remember in any work on therapeutics to have seen a chapter devoted to the treatment of irritable temper. Nor, indeed, is irritable temper as such commonly brought under the notice of the physician for medical treatment. Many physicians must, nevertheless, number among their patients certain irascible individuals the reduction of whose temper to an equable frame would be a blessing not only to themselves but to their associates in business or family life. For the treatment of such people a hint may be gathered from the communication which Sir Lauder Brunton has been persuaded to make to a lay journal. Our contemporary sought advice from several clerical gentlemen as to the best method of preserving perpetual amiability, and, reflecting that the body as well as the soul might be concerned, invited also Sir Lauder Brunton's opinion. He, by his own confession, is in the habit of prescribing what he

calls a "temper-powder," with excellent effect in cases of irritability in gout. It consists of 20 grains of bicarbonate of potash, with 10 to 20 grains of bromide of potash. In cases where the irritability springs from cardiac disease or "is the precursor of headache," "a few doses of bromide of potassium and salicylate of soda give relief and improve the temper." We have no doubt that Sir Lauder Brunton's prescriptions are admirably adapted to their purpose, but we hardly think the columns of *The House Beautiful* a suitable channel for their publication.

#### Dangers of Celluloid Combs.

THE risks attending the use of celluloid combs and collars have been abundantly illustrated by many a tragedy. Again and again have the luckless wearers of such articles been severely or fatally burnt by chance contact with a flame. There is another celluloid danger, however, to which the public is not generally alive, namely, the use of that material so cleverly masked as to be unrecognisable as celluloid save to the expert in such matters. The facts of a recent case brought under our editorial notice were as follows:—A young lady in the country was wearing two handsome and costly combs, apparently made of tortoiseshell, mounted with silver and ornamental stones, while tending a sick domestic pet—country-wise—in the kitchen. She stooped with her head some two or three feet away from a hot fire for a space of about ten minutes or a quarter of an hour. Suddenly her head was seen to be enveloped in smoke. The smouldering material, which proved to be the so-called tortoiseshell, burnt through aprons and other extinguishers, and was at last subdued only by a prolonged douche beneath the kitchen water-tap. The resulting burns were severe and, had not prompt assistance been at hand, might readily have proved fatal. The moral of all this is that the world of women should learn that combs may be sold to them at high prices as tortoiseshell, whereas they are in reality made of inflammable celluloid. The aristocratic tortoiseshell does not blaze and smoulder, and when placed in an actual flame departs from the world in the odour of calm and stoical incineration. Vulgar celluloid, on the other hand, swells up into an inflated mass of hot and vixenish combustion when brought close to a stove, lamp, or other source of heat. Therefore, ladies, be sure what you buy as tortoiseshell is the real thing and not that modified form of gun-cotton known as celluloid.

#### A Judge's "Surprise" at a Medical Witness.

THE easy-going ways of the medical profession are, beyond a doubt, answerable for the loss of a good deal of legitimate income. Take, for instance, the lax methods of medical men compared with those of lawyers engaged in a legal case. Before coming into Court the lawyer either pockets his fee, or assures himself with a reasonable amount of certainty that his costs will be forthcoming should his client win or lose. Woe to the medical witness who is weak enough to give evidence

without a clear undertaking as to payment of fees. Even where his evidence is material to a decision he runs a considerable chance of receiving never a penny in return for his services. That kind of experience comes sooner or later to the young medical man and burns into his soul the conviction of the folly of trusting either lawyers or litigants when it comes to a question of payment of witness' fees. The proper course is for the medical man, when he steps into the witness-box, to refuse to be sworn unless his fees are first paid. It is astonishing how often judges are apt to bring pressure to bear upon medical men under such circumstances, although their zeal for gratuitous justice rarely, if ever, extends to members of the legal profession. Some weeks ago Judge Gwilym Williams, in a compensation case brought against the Great Western Railway, adopted an extreme, and, so far as can be gathered from a report in the *Western Mail*, an unfair attitude towards a medical man in Court who had been subpoenaed by both sides, and who naturally wanted to know who was going to pay for his evidence. The judge is reported to have said severely: "I am surprised at a medical gentleman making so much fuss about his fees in a case of this kind when so much is at stake." Surely, if the magnitude of the case is to be an argument against ensuring the payment of fees, the rule would apply equally to the judge, counsel, solicitors and unskilled witnesses. Subsequently the judge expressed regret for those remarks on the ground that Dr. Evans' evidence was of the utmost importance, but we fail absolutely to recognise the proposition that the rights of a witness are to be upheld or treated with contempt in proportion to their direct value in relation to the merits of a given case.

#### Sanatoria as Public Educators.

THE anti-tuberculosis crusade, however much its achievements may fall short of its aims, is exercising an influence of untold weight in the education of our countrymen in the matter of phthisis and its prevention. Every local committee in this way becomes a radiant centre for the diffusion of knowledge of the highest preventive value in its immediate neighbourhood. A good instance of the awakening effect of the crusade was shown last week in the important inquiry opened at Exeter by the General Purposes Committee of the Devon County Council as to the proposed establishment of a hospital for the treatment of phthisis. The widespread public interest in the question was evidenced by petitions from five towns and a large number of public authorities concerned. Of the latter no less than thirty-two bodies expressed themselves in favour of the proposed hospital. In addition, many prominent men, medical and non-medical, expressed views which will gain the widest publicity by means of newspapers and reports. In this case the Exeter organisation has spread the leaven of useful information not only through Devon, but also through adjoining counties.

### The Late Sir William Mitchell Banks.

ON Tuesday, November 29th, a meeting was convened at the Liverpool Town Hall, under the presidency of the Lord Mayor, to take into consideration a proposal to perpetuate in some fitting and material way the memory of the late Sir William Banks, M.D., F.R.C.S. The meeting was in every way a representative and influential one, and a spirit of unanimity pervaded the whole proceedings. It was everywhere felt that the late distinguished surgeon had deserved well of the community amongst which he had spent a laborious and eminently useful life. It was, and is, felt by many that the Liverpool University itself owes its very existence to him; more so, perhaps, than to any one individual besides. The Lord Mayor proposed: "That a memorial of a permanent character be established to commemorate the name and the services of the late Sir William Mitchell Banks." The proposition was seconded in an eloquent speech by Vice-Chancellor Dale, who observed that a "better idea had occurred to some influential friends of the movement that there should be a lectureship established, permanently identified with Sir William Banks' name and associated with the objects of medical education which he had in view." The idea seemed to "catch on" at the meeting, and at the close a subscription-list was opened, when a considerable number of the gentlemen present liberally responded. There can be no doubt that the movement will be carried to a deservedly successful issue.

### The Pastime of Cycling.

FROM the point of view of the medical man, cycling as a form of physical exercise cannot be too highly recommended, but naturally everything depends upon the way in which it is followed. The method, of course, of the "Clan McScorcher"—the members of which pace the roads at the topmost of their powers, with their noses on the handle bar, and their backs and arms curved like "monkeys on the stick"—need only be mentioned to be condemned; often the youths who thus attempt to acquire the name of "speed merchants," as the term goes, may be met with whose faces, from their cyanosed condition, betoken only too plainly the dangerous physical effort to which they are subjecting themselves. Again, cycle racing is a prostitution of this pleasure-affording, attractive pastime which calls for no further comment, even apart from the direct risk to life to which its followers are exposed. In view, then, of the health, enjoyment, and exercise which pleasure cycling affords, it is regrettable to note that evidence exists of its waning popularity. We presume that the Cyclists' Touring Club may be taken as representing the measure of popular interest devoted to cycling in this country, and yet while a few years ago the membership of this club amounted to nearly 60,000, in the present day it has diminished to half that number. What does this mean? Does it imply that cycling is less attractive as a pastime than it used to be? We sincerely trust that this is not the case; on the other hand, it seems difficult

to account for the serious falling off in the membership of this erstwhile flourishing club. The latter, however, recently announced that they were about to embark upon a new scheme in which they had great hopes of bringing back the popularity which they had lost. This great scheme consists in offering to spend some of the club's hard-earned savings to the extent of £400 in prizes for the discovery of a device for preventing side-slip. We may now expect the railway companies to offer prizes for the prevention of railway accidents. The idea of such a scheme is splendid from the point of view of its impracticability, and it is scarcely needful to state that if the Council of the C.T.C. can suggest nothing better than this to restore the former popularity of the club, the members should take an early occasion to elect other representatives to protect their interests.

### The "Hospital" and the Funds.

THE Editor of the *Hospital* is exceedingly wroth with THE MEDICAL PRESS AND CIRCULAR for not having replied forthwith to his challenge to us to substantiate certain statements with regard to the Hospital Sunday and King Edward's Hospital Funds. He may rest assured that there will be plenty of material for him to work upon before the Ides of March are upon us. Pressure upon space and the verification of facts and figures, so far as possible upon the basis of scanty reports, may or may not be accepted as satisfactory reasons for the delay, but in any case we have not the least intention of being hustled by the editor of any contemporary, lay or medical. The relations of the Royal Orthopaedic Hospital to the Hospital Sunday Fund will require restating, as the Editor of the *Hospital* has failed to grasp our points. We fear our contemporary will have to wait another week, but we note that delay does not prevent him anticipating some of our arguments.

### PERSONAL.

DR. PRIESTLEY SMITH, who has filled the post of Ophthalmic Surgeon to the Queen's Hospital, Birmingham, for more than thirty years, has resigned his appointment. The Committee have accepted the same "with deep regret," and, as a mark of their appreciation of his services, have recommended the Governors that he should be elected honorary consulting surgeon to the hospital.

THE lifework of the late Sir Wm. Mitchell Banks, Emeritus Professor of Anatomy at the Liverpool University and Consulting Surgeon to the Royal Infirmary, is about to be perpetuated by a memorial, the form of which is undecided. We refer more fully to the subject in the previous column.

By a recent decree of the Provost and Senior Fellows of Trinity College, Dublin, a Chair of Applied Chemistry has been established in the University. The first occupant is Mr. E. A. Werner, for many years Assistant to the Professor of Chemistry. His work is well known in the scientific world.

PROF. SIR W. JAPP SINCLAIR, M.A., M.D., has been

lected Chairman of the Universities of Glasgow and Aberdeen Conservative and Liberal Unionist Association for promoting the candidature of Prof. William R. Smith, M.D., to represent these Universities in Parliament.

THE Nobel prize in the Physical and Chemical Sciences Section is, according to the Paris *Journal des Sciences*, likely to be awarded this year to Sir William Ramsay, Professor of Practical Chemistry in University College, London.

AN appeal, signed by the Hon. Sydney Holland, Sir Francis Laking, Sir Frederick Treves, and Mr. Malcolm Morris, has been issued for subscriptions to the fund for the erection of a monument to the late Professor Finsen. The British Committee formed to co-operate with the Danish Committee has received a donation of £50 from the King and of £100 from the Queen. Subscriptions may be paid to the Finsen memorial fund at the National Provincial Bank, 112, Bishopsgate Street, London, E.C.

THE Earl of Rosebery, Chancellor of the University, has given £1,000 to the Institute of Medical Sciences Fund, University of London.

THE Astley Cooper Prize of £300, which is offered triennially for medical research, has been awarded to Mr. W. Sampson Handley, Hunterian Professor in the Royal College of Surgeons, for an essay entitled "Epigastric Invasion of the Abdomen in Breast Cancer."

MR. LYNN THOMAS, C.B., F.R.C.S., has accepted the position of honorary consulting surgeon to Barry Hospital.

DR. DONALD MACALISTER, of St. John's College, Cambridge, has been elected President of the General Medical Council, on the retirement of Sir William Turner.

LADY CHEYLESMORE, wife of the Mayor of Westminster, opened the new building of the Royal Ear Hospital, recently erected at 42 and 43, Dean Street, Soho, on Monday last, at 3 p.m.

WE are officially informed that the Local Government Board of Scotland have appointed Dr. Fred. Dittmar, M.A., M.D., D.P.H., to the office of Medical Inspector, vacant by the promotion of Dr. W. Leslie Mackenzie to be Medical Member of the Board. He is the Medical Officer of Health for Scarborough, and previous to his present appointment he was for some years resident Medical Officer to the City of Glasgow Fever Hospitals, and afterwards assistant to the Medical Officer of Health for that city.

MR. JOHN UTTING, J.P., a medical member of the city council, has been elected to the important post of Chairman of the Port Sanitary and Hospitals Committee of the Liverpool Corporation.

ON November 22nd, the Right Hon. George Wyndham, M.P., Chief Secretary for Ireland, was formally installed as Rector of the University of Glasgow. The Corporation of the city was represented by the Lord Provost, Sir John Ure Primrose, and several members of the town council.

DR. RECLUS, Professor of Operative Surgery in the Paris Faculty of Medicine, has been appointed at his own request Professor of Clinical Surgery in succession to the late lamented Professor Tillaux.

THE following telegram from Sir C. Boyle, Governor of Mauritius, has been received at the Colonial Office:—"For the week ending December 1st, 32 cases of plague, 25 fatal, 2 white."

## Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

### SCOTLAND.

GLASGOW MATERNITY HOSPITAL.—H.R.H. the Princess Louise, whose philanthropic interest in medical charities has been conspicuous on many occasions, attended a meeting in the Grand Hotel, Glasgow, on November 29th, for support of the movement for the extension of the Glasgow Maternity Hospital. For a number of years the work of the hospital has been hindered by lack of accommodation, both for patients and students, and to remedy this the directors have acquired a considerable amount of property adjacent to the present building, on which, in addition to increased accommodation for patients, they intend to provide a school for the practical teaching of midwifery and gynæcology. The sum required to be collected is £54,500, including £14,500 as the cost of the site and £40,000 for new buildings. Professor Murdoch Cameron, after dwelling for a moment or two on the poverty of many of the inhabitants of a great city like Glasgow, in which 30 per cent. of the houses were of one apartment only, said that during the past ten years the hospital had attended 29,013 cases, 90 per cent. of which had been the wives of poor working men. During the same time they had trained 1,244 students and 800 nurses. These men were now practising throughout the country, and those who had comfortable homes were at the mercy of these men and women therein trained and educated for their work. His Grace the Duke of Argyll moved the following resolution:—"That in view of the urgent need that exists for the increased accommodation of patients, and for the training of students and nurses, this meeting resolves to support the Directors of the Maternity Hospital in their efforts to effect both these objects." This was seconded by Prof. A. R. Simpson, Edinburgh, and carried. Lady Ure Primrose moved the second resolution:—"That the meeting do all in its power to raise the necessary funds," which was supported by Rev. Dr. Macleod, and carried.

SCHOOL BOARD CERTIFICATES.—The Dundee Branch of the British Medical Association has passed a resolution maintaining that the responsibility for the supply of medical certificates for absent children rests on the School Board, and recommending medical officers of charities and other public bodies to decline to fill them up. This entirely reasonable action appears to have incensed the School Board authorities, for one of the members in consequence asserted that the medical profession were desirous of foisting two or three of their own number on the Board. He pointed out, what is, we think, sufficiently well known, that until a new Act was in force the School Board had no power to appoint medical men, but this in no way makes the present system of expecting every medical officer to a charity to fill up certificates for non-attendance at school less anomalous.

### BELFAST.

ANNUAL DINNER OF THE ULSTER MEDICAL SOCIETY.—The annual dinner of the Ulster Medical Society was held on Saturday evening last in the Medical Institute, Belfast, when a marble bust of Sir William Whitt, the donor of the Institute, was unveiled by Sir Lauder Brunton, who had kindly come from London for the purpose. The chair was occupied by the President of the Society, Dr. William Calwell, and among the guests present were the Lord Mayor of Belfast, the President of Queen's College, Belfast, Mr. Chance, the President of the Royal College of Surgeons, Ireland; Professor W. Smith, T.C.D.; Sir John Moore, Sir Wm. Thompson, Sir T. Myles, and Professor Lorrain Smith. After the toasts of the "King" and the "Lord Lieutenant" and "Prosperity" to Ireland, Dr. Calwell called on Sir Lauder Brunton, explaining in a few words the history of the Institute and of the movement to provide a permanent memorial of the donor in it. Sir Lauder Brunton, who received a very enthusiastic welcome, spoke of his many years' friendship with Sir William

Whitla and of the personal qualities of kindness and sympathy which endeared him to all with whom he came in contact, of his success as a practitioner and teacher, and, lastly, as a writer who had enriched the whole world by his works. The Ulster Medical Society were under a special debt of gratitude for the Institute; he attached the greatest importance to the opportunities for social intercourse which it afforded and encouraged, for differences of opinion and divided interests were sure to arise in the course of practice which could be smoothed down by the men meeting together in friendly social intercourse. He had the greatest pleasure in unveiling the bust and proposing the health of the donor of the Institute. Sir William Whitla was also received very warmly on rising to reply to his health. He thanked Sir Lauder Brunton from the bottom of his heart for all his kind and flattering words, and said that for all he had done he was amply repaid when he looked into the Institute occasionally in the evening and saw the members of the Society enjoying its use. He gave an amusing account of the modelling of the bust in clay by Miss Kathleen Shaw, the sculptor, and his hope, when he found that the clay had been previously used for a bust of the Primate of All Ireland, that some of his great gifts of oratory might descend on him, but when he tried to express his feelings he found he was common clay after all. The other toasts were "The Dublin Schools of Medicine," proposed by Professor Lindsay, and responded to by Mr. Chance, President R.C.S.I.; Professor Walter Smith, T.C.D., and Sir John Moore, Ex-President R.C.P.I.; "Our Guests," proposed by Dr. Walton Browne and responded to by Sir Lauder Brunton and the President of Queen's College; and "The President," proposed by Dr. Kevin, responded to by Dr. Calwell.

**THE HEALTH OF THE CITY.**—During the four weeks ending November 10th, 276 cases of zymotic disease were notified in Belfast, including 63 typhoid, 70 simple continued fever, 56 scarlet fever, 41 erysipelas, 18 small-pox, 21 diphtheria, 5 membranous croup, and 2 puerperal fever. The deaths from zymotic diseases were 72, and those from phthisis and other diseases of the respiratory system 189. The annual death-rate from all causes was 18.4, an increase of 0.5 over the same period last year.

**THE SMALL-POX OUTBREAK.**—During the past fortnight there have been 10 new cases of small-pox discovered and removed to hospital. Four of these were from one family; two children had suffered from mild attacks and were only found out when another child, unvaccinated, took a severe attack, and the father also became ill. Two other cases of the ten were unvaccinated, an adult and a child of fifteen months. Except for these unvaccinated cases, the general type of the disease is mild. There was one death during the fortnight, an unvaccinated adult of 37, who had come in the previous week. The outbreak has now lasted nearly fourteen months, and there have been 137 undoubted cases of small-pox under treatment.

## Special Reports.

### THE GENERAL MEDICAL COUNCIL.

SATURDAY, NOVEMBER 26TH.

The President, SIR W. TURNER, in the Chair.  
Aosent, Mr. Morris, Mr. Power, Mr. Tichborne.

The Minutes of the last meeting were read and confirmed.

Dr. CATON was elected on the Examination Committee as a member representing the English Branch Council, in the place of Dr. Payne, no longer a member of the Council.

Moved by Sir PATRICK HERON WATSON, seconded by Dr. McVAIL, that the Report of the Examination Committee on the Inspection of the Final Examination of the University of Edinburgh be received and entered on the Minutes.

The Committee in their Report (signed by the Chairman, Sir Patrick Heron Watson) recommended that

As the difference of opinion between the Visitor and Inspector on one hand, and the University on the other, is fundamental as to the nature of the Surgical Examination, and as the Visitor and Inspector have not given any detailed evidence in support of their adverse criticisms, and as some of the Statements of Opinion by the Visitor and Inspector are irreconcilable with each other, the Medical Council should direct that a further inspection be made of the surgical part of the Final Examination in the University of Edinburgh.

Sir JOHN TUKE proposed, and Dr. MACKAY seconded, an amendment to omit certain phrases in the Section of Remarks by the Visitor and Inspector before the Report was entered on the Minutes.

A long discussion followed, nearly all the speakers being of opinion that all Reports of Visitors and Inspectors should be treated with great respect, and should be sent on entire to the Privy Council.

Sir JOHN BATTY TUKE and his seconder sought the permission of the Council to withdraw his amendment in favour of another by Dr. Norman Moore.

Dr. PYE-SMITH moved the closure, and that the Council should proceed to vote on the amendment. Dr. LINDSAY STEVEN seconded, and the motion was carried.

The Council then proceeded to vote on the amendment, which was lost 22—4; 4 did not vote, 3 absent.

It was then put that the Report be received and entered on the Minutes. This was carried.

Moved by Dr. NORMAN MOORE, seconded by Sir VICTOR HORSLEY, and carried: "That the discussion on this Report be adjourned to Monday, November 28th, 1904."

Dr. WINDLE moved that the Report of the Education Committee be received and entered on the Minutes. He clearly explained the scheme it contained. Sir CHRISTOPHER NIXON seconded.

Moved by Dr. WINDLE, seconded by Sir CHRISTOPHER NIXON: "That any well-considered plan which would tend to a diminution in the number of examinations in preliminary subjects of education, and to a unification of standard of those which remain, would meet with the hearty approval of the Council."

Sir VICTOR HORSLEY proposed, and Mr. JACKSON seconded, an amendment: "That while recognising the practical difficulties of unifying methods of testing secondary education, the General Medical Council expresses the hope that the Board of Education may, in considering any system of School Certificates, find it possible to establish a Central Board for the purpose of creating and supervising a single examination of such a standard that it might, in the opinion of the General Medical Council, be recognised as qualifying for entrance to a course of professional study."

This was lost, 18—4; 8 did not vote, 3 absent.

Dr. Windle's original motion was carried.

Moved by Dr. WINDLE, seconded by Dr. PYE-SMITH, and agreed to: "That if the Standard of Examination contemplated in the scheme were such as to be generally accepted for entrance or matriculation by the Universities of England, the Medical Council would be prepared to recognise it as qualifying for entrance on a course of professional study."

Moved by Dr. WINDLE, seconded by Dr. MACALISTER, and agreed to: "That pending the general adoption of a uniform system of educational tests, the Council would welcome the establishment under the Board of Education of a Central Board, for the purpose of classifying examinations according to standard and arranging for the mutual recognition of certificates; and, further, that they regard the establishment of such a Board as highly desirable from an educational point of view."

Moved by Dr. WINDLE, seconded by Sir JOHN MOORE: "That the Report of the Education Committee as modified be approved."

The Reports of the Pharmacopoeia Committee and of the Finance Committee were received and entered on the Minutes without discussion.

The Council then adjourned.

MONDAY, NOVEMBER 28TH, 1904.

The President, Sir WM. TURNER, in the Chair.  
Absent, Mr. Morris, Mr. Power, Mr. Tichborne.

The Minutes of the last meeting were read, amended, and confirmed.

The Council proceeded to the consideration, adjourned from November 26th, 1904, on the motion of Dr. NORMAN MOORE, seconded by Sir VICTOR HORSLEY, of the Report by the Examination Committee on the Inspection of the Final Examination of the University of Edinburgh. The inspection contained an unfavourable criticism on some of the arrangements and methods of the Examination in Clinical Surgery. The Visitor and Inspector also deemed it their duty to point out the desirability, if not the necessity, of the Edinburgh University, with all other teaching bodies, so adjusting its curriculum as to give Medical Students greater facilities than they now seem to possess of gaining a better knowledge of disease and its treatment by clinical work.

Moved by Sir PATRICK HERON WATSON, seconded by Dr. McVAIL: That the Recommendation of the Examination Committee contained in the Report be adopted.

The PRESIDENT, as representing the University of Edinburgh on the Council, made a few remarks in defence of the system of Examination in Clinical Surgery therein. He thought some parts of the Report by the Visitor and Inspector might be regarded as strongly adverse criticism, and some of the statements as of a very sweeping character. He pointed out that the difference among schools in the Examination in Surgery on the cadaver was mainly due to some schools getting more bodies than others, but that every candidate going through the University of Edinburgh must study Operative Surgery.

Sir VICTOR HORSLEY supported the Report and the Recommendations, as the rejections in Surgery at the University of Edinburgh were higher by a half than those in medicine.

An amendment was then proposed by Dr. PYE-SMITH and seconded by Sir JOHN MOORE: That the Recommendation be adopted in the following form: "That the Council direct that a further inspection be made of the Surgical part of the Final Examination in the University of Edinburgh during the year 1905."

Sir CHRISTOPHER NIXON considered that the Council should deal very tenderly with a Report of the Council's own Visitor and Inspector.

Professor Thomson, Dr. McVail, Mr. Brown, and Dr. Lindsay Steven made a few remarks, and Sir G. H. Philipson, as the Visitor in question, said a few well-chosen words in defence of the Recommendations; after which Sir PATRICK HERON WATSON and his Seconder accepted the amendment on the part of the Committee, and the Amendment, which had thus become the sole Motion, was put and carried.

Moved by Sir PATRICK HERON WATSON, seconded by Dr. McVAIL, and agreed to: "That the Report by the Examination Committee on the Inspection of the Final Examination of the Apothecaries' Hall, Dublin (July, 1904), be received and entered on the Minutes." The Report was then adopted. (Same Proposer and Seconder.)

Moved by Sir PATRICK HERON WATSON, seconded by Dr. McVAIL, and carried: "That the Report of the Examination Committee on the Inspection of the Final Examination of the University of Glasgow be received and entered on the Minutes." The Report was then adopted. (Same Proposer and Seconder.)

Moved by Sir P. HERON WATSON, seconded by Dr. McVAIL, and agreed to: "That the Report of the Examination Committee on the Inspection of the Final Examination of the University of Aberdeen be received and entered on the Minutes."

Moved by Sir P. HERON WATSON, seconded by Dr. McVAIL, and agreed to: "That the Report of the Examination Committee on the Inspection of the Final Examination of the University of St. Andrews be received and entered on the Minutes." The Report by the Visitor and Inspector was not always favourable, it

being mentioned, *inter alia*, that it was by no means certain that the method of excluding all the candidates from the wards of the Royal Infirmary for ten days previous to the examination was effective; also that in the oral examination in some cases only one examinee was present; also that the teaching examiner was too prone to show his teaching capacity rather than his examining power. On the other hand, great praise was given to the Examinations in Ophthalmology, in diseases of the ear, throat and nose, and in skin diseases. On the motion for the adoption of the Report being made by the same Proposer and Seconder, Dr. MACKAY, made a few observations in defence of St. Andrews, which were, however, rather traversed by Sir JOHN MOORE, the Visitor, who asked leave, which was accorded, to alter an error in a sentence of the Report, which now reads: "Both Examiners gave fifteen minutes each to the Examination of each of the six candidates." Subject to this correction the Report was adopted.

The Council then adjourned.

TUESDAY, NOVEMBER 29TH, 1904.

Sir WILLIAM TURNER, President, in the Chair.

The Minutes of the last meeting were read and confirmed after an explanation by Sir Hugh Beevor with reference to his signature appearing at the end of the report of the Visitation of the University of Glasgow; he had found out that his signature had been put in the final proof as a matter of form in the office, and the final proof had not been sent to him. He hoped that in future no signatures would be appended without a final proof being submitted.

Sir PATRICK HERON WATSON moved, Dr. McVAIL seconded, and it was agreed to:—"That the Examination Committee be requested to consider their Report on the Final Examination of the University of Edinburgh in conjunction with the results of the additional inspection of the surgical parts thereof directed by the Council to be made in 1905, and to present a Final Report of the second inspection at the November session of the Council in 1905."

Moved by Sir P. HERON WATSON, seconded by Dr. McVAIL, and carried: "That the Report by the Examination Committee on the further reply by the Royal College of Surgeons of England to the Inspector's report on the final examinations of the English Conjoint Board be received and entered on the minutes." The Examination Committee in their Report were satisfied with the alteration in the system of marking recommended by the Court of Examiners, but regretted that the Court of Examiners consider as unnecessary an examination in ophthalmic surgery, which the Committee regarded as being essential, and the Examination Committee did not see any reasons to alter their opinion that a written report on a medical or surgical case was neither useful nor practicable.

The adoption of the Report (same Proposer and seconder) was agreed to, after Sir CHARLES BALL had made a few remarks on the importance nowadays of a training in operative surgery, which he maintained could not be properly taught excepting on the dead body. Sir VICTOR HORSLEY received an affirmative answer from the President as to whether this question could not be taken up next session as a resolution based on this Report.

The Council next proceeded to the consideration (adjourned from Nov. 25th, 1904, on the motion of Sir BATTY TUKE) of the recommendations contained in the last paragraph of the report of the Public Health Committee: "That the Council should refuse a certain application for exemption."

Sir BATTY TUKE, in support of the refusal, thought that the introduction of individual cases was very dangerous, but he wished to withdraw his motion and refer the matter to the Public Health Committee next session.

Dr. LINDSAY STEVEN then moved, and Sir CHARLES BALL seconded, a modified amendment (of which notice had been given): "That should the applicant be admitted to the examination by any of the qualify-

ing bodies without having personally complied with Rule 3, the Council will have no objection to the registration of his diploma when obtained."

Dr. BRUCE, as chairman of the Committee, accepted the amendment, and in answer to Sir VICTOR HORSLEY, who wished to know why the Committee had changed their opinion in this matter, said that it was owing to a communication from Mr. Power, who did not see his way to oppose the amendment.

Dr. MACALISTER, although he believed it was dangerous to grant exemptions, was of opinion that if the Council thought that it was a hard case they could deal with it by accepting the amendment; but he considered that the whole matter should be referred to the Public Health Committee.

The amendment was then first carried, and then carried as a substantive motion. Dr. MACALISTER then moved, and Dr. BRUCE seconded, that the matter be referred to the Public Health Committee to be reported on next session.

The resolution proposed by Dr. MACALISTER, seconded by Dr. NORMAN MOORE, to receive place on the Minutes and adopt the Report of the Pharmacopœia Committee, was then carried.

Dr. NORMAN MOORE then moved, Dr. LITTLE seconded, and it was agreed to unanimously, that two votes of thanks of the Council should be presented: one to Dr. MACALISTER for his services in regard to international uniformity in the pharmacopœial remedies and the second to Dr. Payne, who, on retirement, had presented the Council with a copy of the earliest Pharmacopœia.

Dr. PYE-SMITH proposed, and Mr. TOMES seconded: "That the Report of the Finance Committee be received and entered on the Minutes. This was agreed to, and the report was adopted, after the three propositions it contained had been moved and seconded separately. These propositions had reference (1) to £1,000 received from the builders; (2) to the dental funds; and (3) to a loan from the Pharmacopœia Account.

Sir V. HORSLEY moved, and Dr. MACALISTER seconded that the report of the Preliminary Scientific Education and Examination Committee be received, entered on the minutes, and adopted. This was carried.

Moved by Sir VICTOR HORSLEY, seconded by Dr. WINDLE, and carried: "That the elements of embryology should be definitely associated with morphological zoology and included in the syllabus of Elementary Biology." (Extract from Para. 6 of the report.)

Moved by Mr. TOMES, seconded by Sir V. HORSLEY, and carried: "That the Report of the Medical Companies Bill Committee be received, entered on the Minutes, and adopted with an addition to the Appendix."

Moved by Mr. TOMES, seconded by Sir CHARLES BALL, and carried: "That the Report by the Dental Education and Examination Committee be received, and entered on the Minutes."

In moving the adoption, which was carried, Mr. TOMES, who was seconded by Dr. LINDSAY STEVEN, remarked that the Dental Board of Victoria, which had come into close contact with the University of Melbourne, had made every effort to make its licence up to date.

Moved by Sir HUGH BEEVOR, seconded by Dr. NORMAN MOORE, and carried: "That the Report by the Students' Registration Committee be received, entered on the Minutes, and adopted."

The Council then considered for a long time *in camera* the mode of procedure in the election of a President. When strangers were re-admitted, Sir W. TURNER made a few graceful remarks before relinquishing the Chair, expressing his deep acknowledgments for all the kindness, sympathy, and support he had received from the members of the Council during the discharge of his presidential duties, which last were occasionally, he admitted, of a rather trying character, and asking pardon if, during discussions,

he had, either in word or manner, hurt the feelings of any member of the Council. The President's words were very cordially received.

Sir PATRICK HERON WATSON proposed, and Dr. PYE-SMITH seconded, that Dr. MacAlister be elected President. This being agreed to, the proposer and seconder brought Dr. MacAlister into the Council room, where he was installed in the Chair by the retiring President. Dr. MACALISTER said a few words, thanking the Council for the honour conferred upon him, which he considered the greatest of his life, after which the members flocked round the new President to shake hands with him.

On resumption of business, Dr. MacAlister in the Chair, it was moved by Dr. NORMAN MOORE, seconded by Dr. McVAIL, and carried as an instruction: "That in the opinion of the Council, it is desirable that when new or amended Regulations are adopted by the Council, a formal statement should be placed on the Minutes as to the effect of the new or amended Regulations upon previous Regulations on the same subject."

Leave was then given, on the motion of Sir CHRISTOPHER NIXON, for Dr. Mackay to postpone to the next session his motion, seconded by Sir WILLIAM THOMSON, with reference to Resolution 3 upon the Minutes of May 30th, 1904, in regard to Registers of Dental Students. A communication was then read from the University of Liverpool, asking for recognition by registration in the *Medical Register* of the Diploma in Tropical Medicine of that University. The PRESIDENT suggested as an answer that the Council, in the absence of special legislation on the subject, had no authority to direct the registration as an additional qualification or a diploma on tropical medicine. This was agreed to.

The PRESIDENT answered in the negative Mr. BROWN's question: "Whether the University of Cambridge had communicated to the Council its decision to establish an examination and to grant diplomas in Tropical Medicine and Hygiene."

Moved by Sir JOHN BATTY TUKE, and seconded by Dr. MACKAY: "That the legal advisers of the Council be requested to state an opinion on subsection 3 of Section 3 of the Medical Act, 1886, bearing on the obligation of the Council to forward the Reports of Visitors and Inspectors to the Privy Council in their entirety, irrespective of what they may contain."

At the suggestion of the PRESIDENT, the words: "as to whether an obligation rests on the Council," were inserted, and the motion, as amended, was carried.

A motion by Sir CHRISTOPHER NIXON, seconded by Sir WILLIAM THOMSON: "That in forwarding the reply of the General Medical Council to the letter of the Privy Council of November 1st, this Council desires to bring formally before the Lord President the suggestion made in the memorandum of the President of the Council, dated May 1st, 1903, that the Treasury should be urged to grant a sum sufficient to defray the expenses of the disciplinary functions of the Council" was withdrawn after a brief discussion.

The Council then went into *camera* to confirm the Minutes, and the session terminated.

#### CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held on November 24th, Dr. F. H. Champneys in the chair.

A letter from Miss Oldham, resigning her position as a member of the Board representing the Royal British Nurses' Association, was received and accepted with regret.

A letter was received from the Honorary Secretary of the Metropolitan Counties Branch of the British Medical Association, enclosing a copy of letter addressed by the Branch to the London County Council and asking for the co-operation of the Board with the London County Council in obtaining powers from Parliament to pay registered medical practitioners when called in by midwives in emergencies. Upon

the motion of Mr. E. Parker Young, seconded by Dr. J. Ward Cousins, it was resolved: "That the Honorary Secretary of the Metropolitan Counties Branch of the British Medical Association be informed (1) that this Board agrees that statutory provision should be made for the payment of the services of a registered medical practitioner when called in by a midwife in accordance with the rules of the Board; (2) that the Board has already forwarded a resolution to this effect to the Privy Council."

After consideration of applications for certificates, the names of 1,068 women were passed under Section II. of the Act, and ordered for entry on the Roll.

In Section 1 Sub-Section (2) the Midwives Act states that no woman shall, after April 1st, 1910, habitually and for gain attend women in childbirth otherwise than under the direction of a qualified medical practitioner unless she be certified under the Midwives Act. In regard to this, the Clerk of the Monmouthshire County Council wrote asking the Board's construction of the words "otherwise than under the direction of a qualified medical practitioner."

It was decided that the Secretary should reply to the letter stating that the Central Midwives Board was unable to give a general answer to the inquiry because it was largely a legal question on which no authoritative decision had been given.

Dr. Ward Cousins said that at Portsmouth the County Council had received applications from several women to be put on the list of midwives who had received certificates from the Central Midwives Board, but were unable to read or write. It was decided that though the Board was bound to put on the roll any woman who at the time of the passing of the Midwives Act, had been for at least one year in bona-fide practice as a midwife, and bore a good character, nevertheless the local supervising authorities were not bound to have them on their lists.

#### REPORTS OF THE PROCEEDINGS.

Dr. Cullingworth moved: "That during the consideration of matters having reference to the judicial or penal powers of the Board, or of applications for recognition or approval on the part of institutions as training schools, or of medical practitioners as teachers the representatives of the Press shall be requested to withdraw."

Sir William Sinclair said he was sorry to hear Dr. Cullingworth move such a resolution. He might have waited till the representatives of the Press had given evidence of any want of judgment. The resolution proposed by Dr. Cullingworth required two or three words to make it complete, and those were to exclude the Press on all other occasions; and further, Dr. Cullingworth made so many exceptions that Sir William Sinclair said he really could not see on what occasions Dr. Cullingworth would trust the Press at all.

Mr. Parker Young said it was a protection to the public to have the proceedings of the Board in carrying out the duties of an Act of Parliament reported. He considered that the greater the publicity the better for all concerned.

The consideration of this subject was postponed for reference to be made to the procedure of the General Medical Council.

## Lunacy Department.

### LUNACY IN IRELAND.

THE Fifty-Third Annual Report of the Irish Lunacy Inspectors, which has recently appeared, affords considerable food for thought. From it we learn that a marked increase has again taken place in the numbers of the insane, there being 656 more in the Irish asylums at the end of 1903 than in the previous year, showing an advance of 104 over the yearly average increase for the past ten years—in fact, the increase is the largest

since 1898. All classes of asylums are affected by it except the criminal asylum at Dundrum (which shows a slight decrease), but the yearly augmentation in the numbers has chiefly taken place in the district asylums. The population of which is 9,427 higher than it was 23 years ago. One satisfactory point in so much that is gloomy is that the proportion of lunatics in workhouses, the unsuitable conditions of which for this class of inmates are notorious, continues to show a steady decrease, numbering 16 per cent. in 1903 as against 18 per cent. in the previous year, and 27 per cent. in 1880. This is notwithstanding the fact that an actual increase of 121 took place in the lunatic workhouse population in 1903, the suggested explanation being that a number of aged and dotting persons have been transferred to the lunatic wards from other parts of the workhouses.

It is reassuring to find, however, that the numbers admitted to the institutions of the county show practically no advance (three only) over those of the previous year; in fact, the number of "first admissions" is less by 48. That is to say, there has been no increase in the number of fresh cases of mental disease, and the increment of the asylum population must be due merely to accumulation. Nevertheless, this accumulation has to be dealt with, and we learn from this report that some of the asylums are already overcrowded, while, on the other hand, the necessity for making different arrangements for the lunatic inmates of workhouses is a pressing one. The principle of auxiliary asylums on the lines of that at Youghal is one which those who have had practical experience of the treatment of the insane almost universally distrust, and it would seem that the best way out of the difficulty would be some form of the colony or "boarding-out" system, which has been successful without exception wherever tried, including Scotland. It is sincerely to be hoped that this experiment will soon be legalised for Ireland. In the meantime blocks managed somewhat on auxiliary asylum lines, but in much closer association with the parent asylums, would probably afford the best means of reconciling the dictates of humanity with the shallow pocket of the Irish ratepayer.

The recoveries show an advance on the previous year, the percentage calculated on the admissions being 36.7, as against 35.8 in 1902. The death-rate is slightly higher than in the previous year. In view of the overcrowding alluded to above it is important to note that over one-fourth of the deaths was due to consumption.—a proportion, however, not greatly differing from that in other recent years. A regrettable falling off in the number of autopsies is reported, and we fail to find that any advance has been made with the project of a central laboratory.

Lastly, the return of the Census Commissioners is referred to, the most important point being the decrease in the proportion of idiots as compared to lunatics in 1901, probably owing to more accurate diagnosis.

### ALCOHOLIC INSANITY.

DR. G. M. ROBERTSON, medical superintendent of Stirling District Asylum, in his report for the year ending May, 1904, takes up the question of alcoholic insanity. He alludes to the satisfaction with which those interested in the care of the insane have observed the growing interest of the public in the action of alcoholism in producing mental disease. No single factor sends more men insane in this country than over-indulgence in alcohol. As it is a cause over the action of which absolute control can be exercised, it appears little short of criminal to allow this evil to exist unchecked by the State to the moral and material damage of its citizens. From May, 1894, to May, 1899, the proportion of alcoholic insanity was 20.1 per cent. for men and 6.6 per cent. for women—13.2 per cent. of the total admissions. The difference between the two sexes, whether it be owing to the different customs of men and women or the greater self-control and better morals of the latter, is so great that when the admissions of the two sexes are unequal the total percentage may

give rise to error of deductions from it if it is applied to the general population. The percentage of alcoholic insanity, allowing for this source of fallacy, rose from 13.3 per cent. in the quinquennium under consideration to 18.4 per cent. in 1900, and to 25.8 per cent. in 1901. It then fell to 20.1 per cent. in 1902, 18.1 per cent. in 1903, and back to 13.2 per cent. in 1904. The association of periods of good wages for the working classes with an increase of drunkenness and insanity has already been noticed, while cycles of bad trade and low wages tend to be accompanied by a decrease. An additional explanation of the apparent paroxysm of intemperance now happily passing off has been suggested by Lord Balfour of Burleigh. During the acme of this period the South African War was in progress, and, owing to large numbers of able-bodied young men having enlisted and left the country, the lowest class of labourer, for the first time for many years, got constant work and steady wages. His sudden good fortune was too much for his power of self-control, and the extreme excesses of his class made a substantial increase in the amount of alcoholic insanity admitted to this asylum.

#### LUNACY IN GLASGOW.

THE annual report on the certification of lunatics for the year ending May 15th, 1904, by Dr. Carswell, certifying physician in Lunacy to the Glasgow Parish Council, has just been published. It states that during the year, 886 applications were made to the Inspector of Poor on behalf of persons supposed to be insane, and as a result of the examination of these cases, 544 were certified and 342 uncertified. Of the 544 cases certified, 164 had suffered from previous attacks of insanity, the remaining 380 represent the actual number of persons who became insane for the first time during the year. The actual number of first attacks certified this year is seven less than last year, and the proportion per 100,000 of the population is 63.5, compared with 65.5 last year. This is the lowest production rate for four years. The figures show that at all ages under 45 insanity affects males and females almost equally; that at ages over 45 more men become insane than women, and both sexes become insane in larger proportion to the numbers living at those ages as they advance in years; and that there is a relatively larger number of persons sent to asylums at ages over 45 than under. The ages 15 to 45 are the most important in relation to the question whether lunacy statistics indicate a process of mental deterioration going on in the community; those are the ages of greatest stress and temptation and it cannot be said that a production rate of 8 per 10,000, relating to a section of the population numbering 300,000, is alarming. If the experience of the last four years is normal, as Dr. Carswell thinks there is reason to believe it is, then we are justified in interpreting the steady production rate as meaning that so far as the masses of the people were concerned there was no evidence of an increasing mental deterioration. Turning to the figures relating to the number of population to each public-house, Dr. Carswell shows that the general case is, that with a few striking exceptions a high lunacy rate is associated with a large number of public-houses in the district. The figures before us confirm that general view, but they give no support to the exaggerated views that have been expressed in various quarters that lunacy caused by alcohol is seriously increasing in Scotland.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

#### THE MERE ANALYST AS AN EXPERT IN TOXICOLOGY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Considerable uneasiness has been caused to confectioners and others throughout the country because of a statement published in the daily papers, and attributed to a Belfast analyst, that tartaric acid, so largely used in effervescing drinks and in cake-making, is really

an irritant poison. This, of course, is absurd. There is, I believe, a case on record in which the ingestion of an enormous quantity of the acid—some 600 grains, was followed by death, and indications of irritation naturally existed; but in ordinary cases, where a dose of about twenty grains is taken and when the acid is almost always neutralised to a harmless salt, tartaric acid is not only not poisonous, but of much utility.

The analyst who delivered the *obiter dicta* is, of course, not a medical man, and I think the time has come for the profession to resent very keenly the utterances of mere analytical chemists on questions which pre-eminently require a training in physiology.

Some short time since practically all public analysts were medical men, and all recent reforms in toxicology and in the Food and Drugs Acts were due to their labours. Of late, not only have chemists ousted them from the merely technical part of analysis, for which they are possibly trained, but they now presume to pose as authorities on the most vexed questions of the effects of small doses of drugs on the human organism, and on other matters on which a man with a medical training only has a right to be heard. It is obviously not because a man is competent to detect a fraction of a grain of formalin in milk that he should be considered an authority on the question whether this amount was calculated to do harm.

I am, Sir, yours truly,

J. C. McWALTER, M.A., D.P.H., M.D. BRUX.  
Dublin, November 21st, 1904.

#### HOSPITAL FUNDS AND THE SMALL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If the Hospital Sunday and Hospital Saturday and King Edward's Funds could be merged into a central hospital board, having some real power of control, it is certain that a great number of the small hospitals would soon cease to exist; reason for their existence being evidently lacking entirely. This applies particularly to special hospitals. These institutions may, with few exceptions, be divided into three classes—the unnecessary, the useless, and the sham. Many of them have grown out of the sham into the useful form, although most of these are unnecessary, seeing that the maladies they deal with are all provided for in general hospitals. Can any member of the profession affirm that there exists any real need whatever for separate hospitals for throats, or teeth, or skin diseases, or for deformities, or diseases of the eye or of the rectum, or for stone? Many such hospitals, if not most, have owed their origin to medical adventurers—men eager for wealth or finding themselves failures in practice under legitimate conditions—who have recognised a sham special hospital as a most effective cloak for personal advertisement—advertisement, moreover, paid for by the public out of the subscriptions to the hospital funds. Everyone with any view behind the scenes of medical life in London is aware how successfully this game was played years ago; and how the demoralising spectacle of worldly prosperity gained by such means brought forth numerous imitators. The profession, the public, and the poor would be all benefited by the closure of the majority of special hospitals, and if the incomes of these establishments, with the wasted funds the separate administrations give rise to, were transferred to the general hospitals the pressing needs of these would probably be at once almost fully satisfied.

I am, Sir, yours truly,

HENRY SEWILL,

Cavendish Square, November 30th, 1904.

[We print the above letter with pleasure as it represents a strong view of one side of the question. At the same time we think it right to point out that personal advertisement and professional experience are derived by holders of medical appointments in large hospitals just as much as in small—ED., M.P.&C.]

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The small special hospitals have a claim on the

gratitude both of the medical profession and of the public. Fifty years ago they were the pioneers of specialism when special departments were unknown in the general hospitals. The Golden Square Throat Hospital is an instance in point, for there the foundations of modern laryngology were laid by the late Sir Morell Mackenzie, and there the laryngoscope found its first introduction in this country. Other classic instances are the Blackfriars Skin, the Moorfields Eye and the Soho Women's Hospital—not to mention the National Dental, the Cancer and the Brompton Consumption Hospitals. Many of these institutions started in the smallest and most unassuming fashion and have developed into great centres of scientific work and teaching. Who is to say that the small special hospital of to-day is not to bear fruit one day of equal value to the community. Lastly, under the conditions that rule the hospital medical world of London the only chance of any man not born into the purple lies in obtaining an appointment at a small special hospital. Is the medical alone of all professions to deny the chance of promotion to its rank and file. No, sir, the small special hospitals of London have done and are doing a noble work both socially and professionally.

I am, sir, yours truly,  
A SMALL HOSPITAL PHYSICIAN.

### Obituary.

GEORGE VIVIAN POORE, M.D.

In addition to our obituary notice of last week we have pleasure in publishing the following appreciative memoir of the late Professor Vivian Poore from Professor H. Kenwood, a friend and colleague:—

"As one who was for many years privileged to enjoy the friendship of Dr. G. V. Poore, the sad news of his death comes as a great shock and creates a sense of real and enduring personal loss. His unfailing charm of manner endeared him to all and not a few of us who have been associated with the work at University College and Hospital retain grateful recollections of

assistance in some form or other from one who was always ready with advice, help, and encouragement.

"His eminence as a physician is, of course, known to all, and there are many to testify to his exceptional teaching powers and his popularity with students; but it was mainly in connection with public health matters that I saw most of Dr. Poore. His interest in public health subjects generally was of the keenest, but it was mainly during the latter years of his active life that he gained notoriety by his able and strenuous advocacy of the principle of paying back to Nature the organic matter originally derived from it, by giving directly to the soil our solid and liquid dejecta. As an advocate of the dry system of sewage collection and the subsequent application of human dejecta to the soil in immediate proximity to dwellings, he occupied a position which met with curiously little sympathy from the rank and file of public health workers. The clever and logical advocacy of his views, supported as it was in public debate by exceptional rhetorical and oratorical gifts, rarely carried the entire conviction to the minds of those experienced in public health administration, who recognised (perhaps more than the difficulties and dangers involved in the practical application of his views, save in exceptional circumstances.

"Whatever he wrote or said upon this subject however, was always interesting and well informed, and his experimental work upon the subject in which he took so much interest will for long be studied and quoted as valuable contributions upon a matter regarding which it cannot by any means be said that the last word has been spoken. He was precisely one of those individuals in whom, despite the claims for respect and admiration which much good work of a high order demands the personality of the man predominantly asserts itself and constitutes him first of all an object of warm friendship. With Dr. Poore there passes away a kindly and courtly gentleman, a pleasant colleague, and a true friend."

### Medical News.

#### Medical Sickness and Accident Society.

THE usual monthly meeting of the Medical Sickness Annuity and Life Assurance Society was held at 420, Strand, London, W.C., on November 25th. There were present: Dr. de Havilland Hall (in the chair); Dr. J. Brindley James, Dr. Frederick S. Palmer, Dr. J. W. Hunt, Dr. St. Clair B. Shadwell, Dr. F. J. Allan, Dr. W. Knowsley Sibley, and Dr. J. B. Ball. The accounts presented showed that the sickness experience of the Society was about the same as usual at this time of the year. The recent cold weather produced a rather large number of claims but they were not for the most part of a serious nature, and the business for the whole year will probably show a fair margin in favour of the Society. A considerable number of the members have been laid up through septic wounds, but as all accidents as well as illnesses are covered by the certificates of the Society, full pay has been allowed in every case. Prospectus and all particulars on application to Mr. F. Addiscott, Secretary Medical Sickness and Accident Society, Chancery Lane, London, W.C.

#### Suggested Visit to Paris.

A MEETING of medical men was held in Paris on November 25th, when it was resolved to invite British physicians and surgeons to pay a return visit to Paris. Professor Bouchard, member of the Institut, was elected President of the Paris Committee, and the opinion was expressed that some date early in May—probably between May 7th and 14th—would be most convenient.

#### Badly Ventilated Schools at Burnley.

DR. DEAN, the Burnley medical officer of health, reporting on the measles epidemic, severely condemns the lack of ventilation and overcrowding of class-rooms. In one case he found the air almost unbreathable, the class-room overcrowded, and the infants sleepy and half-poisoned.

**Cyllin and Creolin in the Law Courts.**

A CASE has just been decided in Germany relative to the bactericide and disinfectant called "Cyllin," which is of interest to the medical profession. The right to the word belongs exclusively to the Jeyes' Sanitary Compounds Company, Ltd., of London, who coined it as a substitute for the trade-mark "Creolin," formerly used by them, and which they claim to be very much more powerful in bacteria-killing efficacy than that represented by the original title. Finding that Creolin was still being sold in Germany by the Pearson Company of Hamburg as Jeyes' preparation, the latter company published a statement to the effect that the fluid which they now make (Cyllin) is four times the strength of that which they formerly sent to Germany as "Creolin." Consequent on this statement Mr. Pearson took action against the company in the District Court of Hamburg, and the Court, having referred the matter to the Hygienic Institute of the city, Dr. Kister, of the Institute, was deputed to examine a long series of specimens. That authority reported, as the result of bacteriological experiments, that the defendants (Jeyes) had succeeded in quadrupling the bacteria-destroying properties of the fluid formerly supplied to Germany by them under the name of "Creolin," and that "Cyllin" is eleven times stronger than pure carbolic acid. With this expert testimony, judgment has just been pronounced by the Hamburg District Court in favour of the English company, and the plaintiff's claim dismissed with costs.

**Liverpool Hospital Saturday Fund.**

THE annual report of the Liverpool Hospital Saturday Fund showed the largest advance in any one year since 1873, the total collection from all sources (including £646 4s. 5d. from the ladies' street collection) being £9,007 16s. 4d., as against £8,062 18s. 1d. in 1903, an increase of £944 18s. 3d. The workshop or general fund was still moving upwards, £8,006 14s. 3d. being subscribed, which was £603 16s. 5d. more than last year. The ladies' street collection also showed a very creditable improvement. The total expenses only amounted to £532 10s. 4d., or about 5½ per cent., against 6½ per cent. in 1903. The amount distributed to the hospitals in connection with the Hospital Sunday Fund was £14,850, or £250 more than last year. Of this the Hospital Saturday Fund's share was £8,363 2s. The total number of collections was 3,610; boxes, 2,385; cards and lists, 1,973; and firms using own methods, 152. The total in 1903 was 3,423.

**Royal College of Physicians of England.**

THE Council of the College invite applications for the office of Milroy Lecturer for 1906. The course must comprise not less than "three" nor more than "six" lectures, and are to be given on Tuesdays and Thursdays in February or March, 1906. Applications must be addressed to the Registrar, on or before January 7th, and should contain a statement of the division of the subject selected by the candidate. A copy of Dr. Milroy's "Suggestions" on the subject of his bequest, and information as to the emolument, may be obtained from the registrar.

**Royal Waterloo Hospital for Children.**

THE lady who had so generously offered to endow a cot in the Royal Waterloo Hospital for Children and Women, on the condition that five others will come forward and do the same, has found a worthy supporter in the Executors of the late Mr. Arthur O. Crooke's will, who bequeathed £20,000 to the Hospitals of London and Surrey. These Executors have given the sum of 2,000 guineas to the above hospital, which enables the Board to endow two more beds, so providing three of the number stipulated.

**PASS LISTS.****Royal College of Surgeons, England.**

THE following having passed the necessary examin-

ations and having conformed to the by-laws have been admitted members of the college, viz.:—

L. A. Arnould, T. Bates, and J. A. Bell, St. Bartholomew's; J. Avery, London Hosp.; W. G. Aviss, Birm. Univ.; J. H. Banks, St. George's; H. E. Barrett, St. Mary's; J. F. Beale, B.A.Camb. and London Hosp.; A. R. Beaumont and A. M. Benett, Guy's; C. H. Berry and J. H. D. Bolton, Univ. Coll. Hosp.; A. Blanc and J. H. Burrigge, King's Coll. Hosp.; G. H. Boyden, Edin. Univ., Owens Coll. Manchester, and St. Thomas's; A. C. Brown, St. Bartholomew's; A. H. Burnett, Edinburgh Univ. and London Hosp.; G. Carlisle, Guys; H. Chitty, Univ. Coll. Hosp.; S. H. Clarke, B.A.Camb. and London Hosp.; A. P. Coker, L.S.A.Lond. and Middlesex Hosp.; J. Cook, Univ. Coll., Cardiff, and Guy's; D. K. Coutts, St. Thomas's; A. W. D. Coventon, M.A., B.C.Camb., and St. Bartholomew's; G. F. Dalton, M.D., C.M., Kingston, Ontario, and Middlesex Hosp.; T. S. Davies, Univ. Coll., Bristol; H. R. Dean, Oxford and St. Thomas's; G. De la Cour, Univ. Coll. Hosp.; C. H. Denyer, Guy's; F. L. De Verteuil, Edin. Univ., St. Thomas's, and King's Coll. Hosp.; C. M. Dickinson, London Hosp.; G. R. Ernst, M.D., Rush Medical Coll., Zurich and Berlin Univs.; G. J. Evans, St. Mary's; C. R. B. Eyre, St. Thomas's; R. Felton, Guy's; L. C. Ferguson, St. Bartholomew's; A. R. Finn, St. Mary's; W. J. Fordham, Univ. Coll., Sheffield; F. Forrest, Edin. Univ. and Victoria Univ., Manchester; C. J. Galbraith, King's Coll. Hosp.; H. Hardwick Smith, M.A. Camb. and St. Bartholomew's; A. E. U. Hawkes, L.S.A.Lond., St. Mary's and Univ. Coll., Liverpool; E. C. Hayes, New Zealand Univ. and St. Bartholomew's; S. C. Hayman, Univ. Coll., Bristol; T. B. Henderson, M.B., B.Ch., Oxon, and St. Thomas's; W. R. Higgins, Camb. and London Hosp.; L. Hill, St. Mungo's Coll., Glasgow, and Middlesex Hosp.; J. C. L. Hingston, Middlesex Hosp.; R. F. V. Hodge, B.A.Camb. and St. George's; A. H. Hudson, St. Thomas's; C. L. Isaac, Camb. Univ. and St. Mary's; B. J. F. Jackson-Taylor, Univ. Coll., Bristol, and King's Coll. Hosp.; F. A. G. Jeans, M.A.Camb. and Univ. Coll., Liverpool; E. C. Johnston, Westminster Hosp.; G. F. Jones, Univ. Coll. Hosp.; O. W. Jones, Univ. Coll., Liverpool; A. E. Kerr, Camb. and St. Thomas's; F. C. R. M. Knight, A. E. F. Kynaston and A. Leeming, Guy's; E. B. Lathbury and E. Leverton-Spry, St. Bartholomew's; G. Laurence, Univ. Coll., Liverpool, and St. George's; W. Lister, Univ. Coll., Leeds, and St. George's; A. S. Littlejohns, Camb. Univ. and Guy's; J. MacArthur and R. H. Miller, St. Mary's; J. McCrae, B.A., M.B., Univs. of Toronto and Montreal; J. A. McIlroy, Birm. Univ.; W. T. P. Meade-King, Guy's; W. M. Mollison, M.A., B.C.Camb., and Guy's; W. P. Morgan, M.A.Camb., B.Sc.Lond., Univ. Coll., Cardiff, and St. Mary's; J. F. Murphy and J. Papa Nicolas, London Hosp.; A. Nell, Ceylon Medical Coll., Univ. Coll., and Charing Cross Hosp.; L. E. C. Norbury and E. W. Parry, St. Thomas's; C. W. O'Brien, St. Bartholomew's; C. E. Palmer, B.A. Camb. and St. Thomas's; C. Parker, L.R.C.S. and P. Edin., L.F.P.S.Glasg., and Westminster Hosp.; R. N. Poignand, B.A.Camb. and St. Thomas's; L. E. Price, Birm. Univ.; G. H. Rees and F. Rogerson, Guy's; A. Reute, Univ. Coll., Liverpool; H. G. Sievwright, Univ. Coll., Cardiff, and St. Mary's; J. D. Sinclair, Edin. Univ.; W. H. Smalles, Leeds Univ.; G. R. Southwick, M.D., Harvard and Boston Univs.; M. Spotswood, Liverpool Univ.; C. M. Stevenson, Guy's; H. V. Swindale, Middlesex Hosp.; A. G. Sworn, Univ. Coll. Hosp.; W. A. Tatchell and J. Turtle, London Hosp.; R. J. C. Thompson, St. Thomas's; A. W. Wakefield, Camb. Univ. and London Hosp.; T. R. Waltenburg, M.A.Oxon., B.A. Durh., L.S.A.Lond., and Owens Coll., Manchester; A. C. Warren and J. K. Willis, B.A.Camb. and St. Bartholomew's; R. G. Williams, B.A.Camb. and St. Bartholomew's; R. A. Worthington, Camb. Univ. and London Hosp.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office, these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**PENSATOR.**—We have carefully considered our correspondent's offer, but, regretfully, we are compelled to decline it.

**M.R.C.S.**—Our correspondent will see that the matter to which he refers is commented upon in our editorial columns.

**M.D. (BRUX.)**—Application should be made to the Home Office.

**PRACTITIONER.**—The dispute which, it appears to us, is a trivial one, should be submitted to the arbitration of a mutual friend.

**STABILITAS (Devon).**—If the patient refused to follow your instructions and to wear the splint, your responsibility as to results is clearly waived. Any action he might bring would be precluded to failure, although it might involve you in a good deal of trouble and annoyance. The best way in dealing with such a patient would have been to point out the possibility and the likelihood of bad results if your directions were not obeyed, and to have washed your hands of the whole case when he remained obstinate. Many an ununited fracture has been brought about by mulish obstinacy of that kind.

**W. G. LAMBERT (Luton).**—The case of the medical man who wants a suture only upon rare occasions is exactly met by the aseptic threaded needles now to be bought in sealed glass tubes which are broken at one end when wanted, and the ligature and needle taken out.

### ORIENTAL GRATITUDE.

The *Daily Telegraph* reports that according to a despatch from Kittanning, Pennsylvania, Dr. C. A. Flower, who was mysteriously called to St. Louis a week ago, returned loaded with Oriental presents and documents to show that he had been appointed house physician for life to the Rajah Tipoo Sahib, a potentate of India, who after seven years' search found the physician who dragged him from under a camel and saved his foot from amputation. Dr. Flower, who is a wealthy man, says he will go to India in April and spend the remainder of his life there.

**DR. FIELDEN.**—Your paper has been marked for early insertion. Dr. C. H. B. (Brighton): We regret our inability to insert our correspondent's letter as it would open up a religious controversy, which would be out of place in a medical journal.

**RUTHERGLEN.**—The National Association for the Prevention of Consumption was inaugurated at Marlborough House, under the Presidency of his Majesty the King, when Prince of Wales, on December 20th, 1898.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY DECEMBER 7th.

**OBSTETRICAL SOCIETY OF LONDON** (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Sir W. J. Sinclair, Dr. Lewers, Dr. Williamson, Mr. J. D. Malcolm. Short Communication:—Lieut.-Col. Sturmer: On a Case of Abdominal Gestations. Paper:—Dr. W. Tate: Three Cases of Intestinal Obstruction following Operations for Fibroid Tumour of the Uterus, with Special Reference to the Choice of Operation.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. A. H. Tubby: Clinique. (Surgical.) 5.15 p.m. Mr. J. Bland Sutton: The Surgery of the Uterus. 7.15 for 7.30 p.m. Annual dinner at the Trocadero Restaurant, Ficcaddilly Circus, W.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—5 p.m. Demonstration:—Dr. W. Wingrave: Ear.

THURSDAY, DECEMBER 8th.

**BRITISH GYNECOLOGICAL SOCIETY** (20 Hanover Square, W.).—8 p.m. Specimens will be shown by Dr. Macnaughton-Jones, Prof. J. Taylor, Dr. Eider, Dr. R. T. Smith, and Dr. E. Fenwick. Paper:—Mr. W. Alexander: Adenoma of the Endometrium (illustrated by microscopic sections, photographs and lantern slides).

**BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY** (20 Hanover Square, W.).—5 p.m. Paper:—Dr. N. H. Forbes (Tunbridge Wells): Observations on the Climate and Health Resorts of Scotland.

**OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM** (11 Chandos Street, Cavendish Square, W.).—8 p.m. Clinical Evening. Cases and Specimens will be shown by Mr. E. H. Jones, Mr. G. W. Roll, M. A. Lawson, Mr. A. H. Thompson, Mr. D. Marshall, Mr. J. H.

Parsons, Mr. G. W. Thompson and Mr. E. Chatterton, Mr. G. Costes, and Mr. J. W. Tomlinson.

**HARVEIAN SOCIETY OF LONDON** (Stafford Rooms, Titchborne Street, Edgware Road, W.).—8.30 p.m. Discussion on the Treatment of Pulmonary Tuberculosis (opened by Dr. Mackenzie). Sir W. Broadbent Bart., Dr. J. K. Fowler, Dr. S. Thompson, Dr. W. Ewart, Dr. C. Bate, Dr. Maguire, Dr. J. J. Perkins, Dr. J. E. Squire, and others will take part in the discussion.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchings: Clinique. (Surgical.) 5.15 p.m. Dr. P. Stewart: Paralysis of the Cervical Sympathetic.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Dr. G. N. Meschen: Skin Disease in Children.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture:—Dr. P. W. Price: Mitral Stenosis (illustrated by cases). Post-Graduate Course.)

FRIDAY, DECEMBER 9th.

**CLINICAL SOCIETY OF LONDON** (25 Hanover Square, W.).—8.30 p.m. Papers:—Mr. C. Wallace: A Series of Intussusceptions in Children.—Mr. H. White: A Case of Acute Rheumatoid Arthritis.—Dr. R. Abrahams: On Arthritis Deformans and its Allies.

**EPIDEMIOLOGICAL SOCIETY OF LONDON** (11 Chandos Street, Cavendish Square, W.).—8.30 p.m. Lecture:—Dr. Nuttall: Ticks and Tick-transmitted Diseases.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. H. W. Dodd: Clinique. (Eye.)

TUESDAY, DECEMBER 13th.

**THE MEDICO-LEGAL SOCIETY** (in the Rooms of The Royal Asiatic Society).—8 p.m. Exhibition of four Medico-Legal specimens by Dr. Harvey Littlejohn. Discussion: Degeneration: Its Causes and Prevention—with reference to the proposed Sterilization of certain Degenerates. To be opened by Dr. Robert Rentoul.

## Vacancies.

Stirling District Asylum, Larbert, N.B.—Assistant Medical Officer. Salary £150 per annum, with board, &c. Applications to the Medical Superintendent.

White Moss Sick and Accident Society, Skelmersdale—Medical Officer. Salary £200 per annum. Applications to the Secretary London Hospital, Whitechapel, E.—Medical Registrarship. Salary £100 per annum. Applications to E. W. Morris, Secretary.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 per annum, with board and lodging. Applications to Wm. H. Sands, Secretary.

Nottingham General Hospital.—Assistant House Physician. Salary £100 per annum, with board, lodging, and washing in the Hospital. Applications to the Secretary.

Nottingham General Hospital.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing in the Hospital. Applications to the Secretary.

The Victoria Hospital for Burnley and District.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing. Applications to 7, Grimshaw Street, Burnley.

County of London.—Assistant Medical Officer. Salary £500 per annum. Applications to The Clerk of the Council, County Hall, Spinning Gardens, S.W.

## Appointments.

DEVINE, HENRY, M.R.C.S., L.R.C.P. Lond. Assistant Medical Officer at the Wakefield Asylum.

GROVES, ERNEST W. HER, M.D., B.S., B.Sc. Lond., Demonstrator of Anatomy at University College, Bristol.

SAVILL, AGNES F., M.D. Glasg., M.R.C.P. (Irel.), Honorary Assistant Physician to St. John's Hospital for Diseases of the Skin, Leicester Square.

THOMSON, WILLIAM TRAILL, M.R.C.S., L.R.C.P., House Surgeon to the Warneford Hospital, Leamington.

TOVEY, ARTHUR, M.R.C.S., L.R.C.P. Lond., Clinical Assistant at St. John's Hospital for Diseases of the Skin, Leicester Square.

## Births.

DARGAN.—On Nov. 22nd, at 45 Stephen's Green, East, Dublin, the wife of William Dargan, M.D., of a son.

## Marriages.

POPE—OWLES.—On December 1st, at the Parish Church of St. Mary's, Barnes, Edwin Lonsdale, third son of Alfred Crosby Pope, M.D., of Cliftonville, to Florence Ada, second daughter of Charles Henry Owles, of Scarth House, Barnes.

WOODS—HAMPTON.—On Dec. 1st, at the Parish Church, Ewelme, Oxon, Major Albert Edward Woods, Indian Army, Assam Commission, of Bushey, Herts., youngest son of the late W. H. Woods, M.D., M.A., T.O.D. et Oxon., Surgeon R.N., to Audrey Katherine Mary, elder daughter of the late Prebendary E. K. Hampton, rector of Cradley, Herefordshire, and of Mrs. Hampton, Ewelme.

## Deaths.

MOTT.—On December 2nd, at "Wilderhope," Sedlescombe Road, St. Leonards-on-Sea, Dr. Charles G. Mott, eldest son of the late Charles Mott, of Church Streeton, Salop, in his 86th year.

SCRIVEN.—On December 2nd, at Abberly, Stourport, John Swain Scriven, M.D., B.N., aged 68, late of Duffield, Derby.

### AN OBSCURE FORM OF ALCOHOLISM INVOLVING IRRESPONSIBILITY. (a)

By T. CLAYE SHAW, M.D., F.R.C.P.

OF all the causes or mental conditions which eventuate in murder or self-destruction, none is so frequent or powerful as drink, whether acting directly or indirectly. The imbecile or degenerate is easily led into crime by impulse when he has had drink, but under ordinary circumstances his very stupidity makes him tolerant—or indifferent—to anger-stirring causes, which would strain the balance of a higher equipoised intellect. Jealousy and revenge will hesitate for years on the brink of action, but they plunge boldly into accomplishment under the compelling force of drink. The scientific, calculating murderer is rare, and he is, as a rule, careful in his methods, and patient and deliberate in his tactics; he knows that alcohol would lead him to carelessness and risk of failure, and he keeps away from excess of it. In all ways drink is the beginning of the end. It has had its good results when leading to babbling by the accomplices in unlawful enterprise, but it is the ban of secret societies, and its powers of denudation are so well recognised that no one who is a slave to it can be trusted, for henceforth the veil is torn away from the inner mind, and he has lost the proprietorship of himself.

So immediate is the connection between drunkenness and crime that all the details of it should be well analysed with the view to explaining the question of responsibility, and I propose to draw the attention of the Society to one phase where the signs of inebriety are so masked (though the real loss of inhibition is intense) that only by a special consideration can we come to a right conclusion as to whether the individual is to be held responsible or not. One reason why secret societies flourish best abroad is that drunkenness is more rare. I am not a Freemason, but it has often struck me as strange that out of the thousands of male patients with whom I have been brought in contact, not one has ever divulged by sign or word any one of the mysteries of that very close corporation. To the uninitiated the fact suggests that either the obligation to secrecy is so overpowering as to be an unassailable inhibition, or else that there is no secret or mystery to disclose.

The question of responsibility in criminal cases—which it is, understand, the proprium of the jury to decide—has perhaps a different meaning as applied medically and legally. The law takes no notice of a man getting drunk as long as he is not incapable or disorderly, and it holds him responsible for his actions, which seems to be logical; but the physician knows that when a man is drunk he is not medically responsible, his voluntary actions become reduced to impulsive ones, he acts upon motives which in his true character

would have been restraining ones. Law and medicine are not likely to agree, therefore, upon this question of responsibility until the former recognises that character is the ultimate cause of will, and that whatever changes the character modifies the will, and therefore changes the conditions of responsibility.

In the earlier stages of intoxication we notice how the upper centres of the brain become involved, at first showing instability (which many mistake for brilliancy), then going on to incoherence, and finally to exhaustion or to coma due to toxamia. After a time, varying with capacity for elimination of the poison, resistive power of the nerve-elements and other causes, the intellectual paralysis ceases, and the parts resume function in the inverse order from that in which they disappeared, *in the majority of cases*; but there is a class where this complete recovery does not really occur, though the individuals regain the power of the ordinary reflex brain functions to so complete a degree as to deceive those with whom they are usually in contact, whilst they are at the time in a state of minus inhibition, and are really very dangerous persons both to themselves and others. To the ordinary observer they would pass for sane persons, but they are really unfit for responsibility, and their acts are more like those of somnambulists, or of persons in the stage of recovery from an epilepsy.

Some time ago the head of a large Government institution asked me the explanation of a condition which he occasionally found in some of the workmen, and which was attended with dangerous results, though the condition, which he attributed to drink, was of a character very special in its nature, and characterised by absence of many of the usual indications of intemperance. The rules at this institution in question are very drastic on the subject of intemperance on the part of the officials, and it transpired that though the workmen did not (perhaps could not) indulge in drink by day, they did so exceed at night, in the hope that probably the effects would not be visible the next morning, and that they would be able to carry on their duties undetected in their bad habits. On more than one occasion it was reported to the chief that men who had come in to work, to all appearances in a proper condition, had in the course of the day committed acts foreign to their previously understood nature, and in more than one instance of a suicidal character. In particular, one man, who was an old-established servant, came in to work as usual, but after a few hours made an attempt to poison himself by oxalic acid. It was found on inquiry that the man had done his work as usual, and been able to converse; though how far his intercourse with other people had gone was not stated: probably it was not much beyond slight references to the usual work or the commonplaces of the institution. It appeared afterwards that the man had been a heavy night drinker, but had always been punctual on duty in the mornings.

It has occasionally been remarked that people who have left off drinking for a short time have become suicidal or even insane when it might have been supposed that the ill-effects of the drink should have disappeared, though as a fact the higher centres would appear not to have regained their lost power, and in

(a) A Paper read before the Medico-Legal Society, London, November 8th, 1904.

reality an impulsive state was present. I have often remarked in lunacy practice that the insane symptoms have come on after the drinking habits had been discontinued for a few days or even longer, and though it would have been difficult to have demonstrated that these people were still under the influence of drink, and therefore impulsive and uncertain, there could be really no doubt of it in the light of subsequent events. These conditions are always very puzzling to those who meet with the victims in the apparently sane intervals, and without doubt they have been the cause of miscarriage of justice before now, because the persons so suffering have been judged to be in the possession of faculties to which they were really not entitled.

It would not be difficult to propose theories for the interpretation of these cases. It might be supposed that between the intervals of drinking and the appearance of the insane or dangerous symptoms and acts the patient had been unable to take food and rest and therefore had become weak, though possessing his faculties because he showed no prominent signs of perturbation; or that possibly during the interval some ptomaines had been developed which caused the subsequent explosion; and this is a by no means improbable explanation, though pathology is as yet scarcely ripe for this interpretation.

I remember being called in to see a gentleman whose delusions (of an exalted nature) were very prominent. I suspected that the condition was of alcoholic origin, and so it turned out, but I had considerable difficulty in eliciting the fact from the friends, because they said that though he used to take a good deal, he had recently not taken any, and therefore alcohol could have had nothing to do with it. Over and over again I have seen cases where alcohol has produced suicidal or homicidal conditions, an interval elapsing between the cessation of drink and the outbreak of the attack, nothing wrong being in the meantime noticed by casual observers. Please note that I do not mean to say that a proper examination would not detect some abnormality or impairment of function, but that to those in his casual surroundings, judging only by the way in which methodical or ordinary routine duties were performed, there seemed to be no change. Minute investigation would probably have disclosed incapacity for attention to new subjects, irritability of temper, instability, and change in emotional tone, all pointing to an impulsive condition and loss of inhibition.

Clinically we note that the effects of alcohol are either immediate in producing the delirium and excitement familiarly known as drunkenness, or in chronic changes which gradually set up organic faults in the nervous and general system, leading to slow loss of normal function, or else in the condition which I am describing, and which has not hitherto received the attention it deserves. I can best describe the state as one akin to shock of a partial kind, as if, whilst leaving the lower centres free to act, the upper centres were for the time in a greater or less degree of paralysis, the general condition of inanition of the system with its impairment of appetite and want of proper sleep causing a depressed emotional tone, and perhaps a distorted functioning of such parts of the higher centres as may be capable of action of some sort.

A parallel course is not uncommonly seen in mental shock on the receipt of bad news, where some time after the stunning effect of the primary blow, the usual organic functions being in the meantime performed as is customary, other signs of irregular mental processes appear, due to the *gradual* re-integration of centres that have been profoundly, but not irretrievably, damaged.

That illegal acts are not infrequent (indeed are only to be expected) in other conditions where, the lower centres being left in action, the upper ones are partially or wholly incapacitated, is well shown in a case which came under my notice, of a gentleman who was indicted for indecent exposure before some children

in the street. Evidence was to the effect that this gentleman, who was said to be rather addicted to stimulants, had an attack of the nature of a fit, and that a short time after when in the street, he undid the buttons of his trousers in the presence of some children and passed urine publicly. I had little difficulty in showing that the act was merely a reflex one, done without premeditation, and indeed in all probability unconsciously. Owing to fluid drinking, the bladder had become surcharged, then came the fit and its after effects, which set up a subconscious condition, whilst the sensation of stress of urine put in action the usual reflex act of unfastening the dress, &c., regardless of the public circumstances under which it was done. The man was acquitted of criminal intent, owing to temporary disablement from disease.

In order to understand this class of cases, we have only to consider the doctrine of evolution propounded by Dr. Hughlings Jackson. The highest brain structures are the last to be evolved; they represent the most complete development of inhibition and will. In the acquisition of habits and of business they are regulative and determining, but this co-operative function once brought about, the carrying on of the process is relegated to lower centres which are able to perform unaided the work which has been put upon them; they are more automatic, less voluntary, more organised, than are the structures above them; they are also less liable to impairment by poison (such as alcohol) and disease, and a little consideration will show how many of the ordinary exchanges of conversation and action in social life are but the exercise of these subordinate agents.

"Man thinks little and thinks seldom," says Wundt. Were it not so the fatigue of life would be too great. Much repetition reduces the emotional tone so that we react without strain, almost without consciousness, processes which may have cost much thought and much attendant feeling to acquire.

When will-power and the higher mental faculties such as attention are masked, the lower or subconscious faculties still react in obedience to external or internal stimulus, and this form is either of a simply reflex character, or it issues in impulsive display. Action on impulse is often of a dangerous character, sometimes it is conservative. It is the mode of action of the untutored mind of the child and of the mind which has fallen from its high estate. It is the mode of the hasty and impetuous, and it is the method adopted by Nature for the safety or destruction of the individual at a crisis, issuing sometimes in the one, sometimes in the other. Certainly it is the action of the incomplete mind, and therefore it connotes irresponsibility.

The routine of life is attended with so little vivid consciousness that it is often difficult to say what has transpired, so little attention do the customary processes call forth, and even in the best educated classes, where there is wider orientation of thought owing to greater range of associations, the same reduced process is at work during the greater part of the social life. In fact the higher centres are out of function for long periods at a time, and the coruscations that surprise the ordinary person are but the flashes of light rendered visible when the chief part of the greater centre is obscured.

To define accurately the line of margin between responsibility and non-responsibility is impossible. Men may write coherent letters, may dictate the disposal of their property and of their remains, may go about their ordinary work and social observances, and yet be meditating suicidal or homicidal acts all the time; there is no key to the inner life and motives of a man beyond his acts, and even these can only be relatively estimated. When they (the acts) clash with the ordered social codes we must conclude that the actor is either criminal or insane, or of some innate mental peculiarity; in the former and latter conditions he may or may not be responsible; in the middle term he is certainly not.

*Post-mortem* examination of any brain would show

imperfection. It is a fact that microscopic exploration shows defects and deteriorations in what have been considered to be thoroughly healthy minds, and if so, who shall determine the effect of these intimate, if minute, lesions upon processes of mind? To me they account for many of the shortcomings of which we are ourselves conscious, but of which the outside world is ignorant and refuses to condone.

A well-known present-time actor said to me the other day that the greatest difficulty connected with the stage was having to perform a part when under the stress of worry or anxiety, and yet the audience would know nothing of this inner mental state obscured to public gaze by the function of subordinate centres which they are all the time mistaking for the higher processes, which are in reality very differently occupied. If men would only recognise how uncertain their responsibility is, how incapable they often are to form correct judgments where their own interests are concerned, and how vital it is for the community that they should seek the advice of others whose higher centres are unimpeded by personal considerations, there would be less crime and fewer mistakes. He who goes to his lawyer, his doctor, his priest, or his friend obtains relief because he is substituting for a limited and untrustworthy hierarchy the judgment of an unbiassed mind, free to act because recognisant of the conditions involving responsibility.

It is the knowledge of the imperfect integrity of brain structure in the highest regions which often causes conflict between the lawyer and the physician; the former sees the codes transgressed or evaded, and would make the individual responsible because there is apparently nothing wrong in the ordinary reflexes of social life; the latter knows that the highest and most delicate centres are rarely complete and able to function regulatively, and he therefore hesitates before allowing responsibility.

Incomplete function in any other viscus than the brain is every minute before our eyes, but as it rarely leads to anything beyond inconvenience to the individual it is not of so much importance to the community; but when the brain is impaired no one can forecast what will happen to the individual, or to society.

I look upon the law-lists as evidence more of disease than of wickedness, and the lawyer and the physician as allies in the corporeal and spiritual treatment of the infirmities of crime and insanity. It may be objected to the above interpretation that punishment often prevents the repetition of crime. This I quite admit, but it has nothing to do with the question of responsibility. The conditions of punishment often act medically and enable a disordered or impaired organ to recover its equilibrium; in some cases punishment comes as a relief, the individual feels that his debtor and creditor account is balanced, stress is relieved, and the overburdening of a paralysed centre is cast off; but to proceed to the ultimate resort of doing away with the individual for all time is a process which should only be carried out under the most particular circumstances; in my opinion, the extreme penalty of the law should rarely be visited on women; they are too delicately organised, their mental integrity is too easily destroyed, their impulses and emotions are beyond our ken, and therefore we can only judge them by an inadequate standard.

Is it not for medicine to determine the conditions of responsibility at the time, and for the moral physician, the lawyer, the toll to be paid?

### SOME CLINICAL EXPERIENCES.

By WILLIAM H. PEARSE, M.D.Ed.,  
Consulting Physician, Plymouth Public Dispensary.

*Verge of Poisoning.*—A little personal experience of one's own case may be worth recording, as it suggests truths accurately observed.

I was perfectly well and in the best of spirits on a

certain day; after a light lunch, I took a pleasant journey of eight miles by rail into the country, where with friends I had a light tea, but including Devonshire cream and stewed bottled prunes. I am inclined to think that the cause of my illness was more in the bottled prunes than in the cream. On returning home, I felt uncomfortable, took a cup of *café noir*, going to bed at 11.30; a feeling of nausea came on; about every four minutes a severe pain extended round the lower ribs, and which lasted, on each occasion, about one minute; the pain was most severe, seemingly, in the liver. The pain came like an even band around the ribs. I now and then drew a deep breath to find out if any inflammation existed in the pleura or surface of the liver. After three hours of such feeling of nausea and pain, associated with much depression, I poured up, three or four times, great streams of vomit, and in ten minutes felt well.

What is interesting, pathologically, is the wide region of the pain, and especially the very marked pain in the liver. The hypothesis arises, that the cream or prunes passed slowly into a mode of "poison"; that the "unconscious memory and will" of the cells of the liver, resisting the entrance of inharmonic modes and motions—"poisons"—into the system, passed into a heightened action, with the evolution of what one may call a "mode of motion," a "will" resistance—pain. I ate the cream between 5 and 6 p.m., but did not vomit until 3 a.m.; thus we have a record of the time involved in such processes of poisoning. The case is interesting in another aspect, *viz.*, as illustrating the phenomena of epigastric neuroses and indigestion of neurotic type, the aspects of which are so very varied, and which, without much care, and without a wide general view of many functions and their correlations, are apt to lead us astray, both in diagnosis and treatment.

*Arterial Embolism.*—Thirty years ago a gentleman, *æt.* 50, of fine physique and of active habits, carried a heavy Portland vase down one and up another flight of garden steps. I was called the day after; he was in bed. The heart's action was rapid and most irregular. I gave him entire rest for a week. From that day to now the heart's action has been irregular; but in my very numerous examinations during thirty years, I have never heard a bruit. In 1890, the heart's action became, for a few weeks, slow, the pulse sometimes from 50 to 60.

The general health during thirty years has been good. He has had, however, in two or three winters, some bronchial attacks, and, rarely, a little diarrhoea.

In January, 1902, he fainted, or semi-fainted. I found the heart most irregular and feeble in impulse; the left thigh and leg were cold. I could find no pulse in the left femoral artery, nor in the iliac as far as I could reach over and above the groin. The left iliac and femoral arteries seemed blocked. The leg and thigh swelled greatly for two or three weeks, the skin being very tense; during the same period, the patient suffered much pain over the gluteal region and back of thigh, seemingly due to the compensating expansion of the arteries there.

There was never any sign of gangrene of the toes. The tension of the limb remained for a year, and some swelling of the limb remains. He wears an A1 Martin rubber bandage, and leads

an active life, making no complaint about his limb.

At the time of the embolism he was kept in bed for three weeks, the limb being swathed in cotton wool. I sought to keep up the body temperature, of 98.4° only, around the limb, to allow no extreme of heat by hot jars, and the avoidance of winter cold.

The patient has pretty continuously taken caffeine and Oppenheimer's Glycero-phosphate Palatanoids, each holding  $\frac{1}{170}$  of a grain strychnine.

The patient's pulse now is about 75; heart's impulse of fair power; theirregular rhythm remains. He walks about with great comfort, and enjoys an hour or two light gardening daily.

I have interdicted all standing on steps to trim his over-head vines; he clunks—Eastern fashion—when gardening.

I remember a child, a year old, who having had, without known cause, one profuse stinking motion, collapsed to such a degree that embolism having happened during the collapse, several of its toes gangrened and came off. The diarrhoea, which continued after the primary onset, could not be arrested; the motions were stinking. I advised an egg-spoonful of lemon juice four times a day. In two days the child was well of the diarrhoea, and the fœtor was natural. This free use of lemon juice or lime juice I very largely practised in the chronic diarrhoea and dysenteric diarrhoea of the natives of India, and with the happiest results.

*On Reducing Fat.*—E. S., æt. 19, came in June, 1903; she weighed 197 lbs. She had taken for nearly a year, thyroid extract and Blaud's pills, but without benefit. The menses had been absent a year.

It was obvious that the thyroid had not balanced the correlations of her functions and system. I could make but a guess, in this orderly, obscure, and profoundly deficient correlation. I thus continued the Blaud's pills, also I kept the bowels fairly regular by Pil. Aloes et Fer., and for the system's general healthy metabolism I ordered the juice of two lemons a week.

But I had read somewhere of benefit following the use of thymus gland; so in place of thyroid I gave thymus extract. At somewhat regular intervals since June, 1903, her weight has been 197, 190, 189, 182, 174, 171, 167½, 170, 168, 162 lbs., a gradually ~~occurring~~ decrease of 35 lbs. in ten months.

Her menses were absent for two years, up to January, 1904; they appeared once, and have again ceased.

The gradual decrease of weight seems to indicate that the thymus may have had some influence for good. The girl's whole mental condition has improved, and she is equal to the duties of active domestic service.

One need not enlarge on the profound and complex, yet orderly, correlations of the structures and functions of the system; but we can always go a long way toward balancing these active energies and functions by attention to the *primæ viæ*, the great organic tract; the daily action of the bowels, established slowly and the habit formed, influences for good the whole system; every function is promoted toward harmonious correlation by the just activity and action of the great organic tract.

Disease, one may say, is grandly *general*;

secondarily, local. This truth is recalled to memory on a view of the prospectus, lately circulated, of the vast list and nomenclature of "different" diseases of the skin!

But the principle was vividly forced on me forty-five years ago and after, when I saw the night blindness, the anæmic cardiac bruits, the ulcerations of the legs, the ulcerative dysenteric diarrhoea, and other malconditions of the natives of India disappear, after the free use of "acid fruits"—lime juice, tamarind, &c.

The *general* nature of disease is most strongly and continuously forced on my attention here, in the great stream of præphthisis and phthisis which passes before me. For years even, before phthisis exists in the lungs, the young people will, in different cases, suffer from a sense of "weakness," or sense of coldness, or indigestion, or disturbed menstrual function, or failure of appetite; and these præphthisical symptoms, variously mingled in different cases, will be correlated to certain well-defined physical types of the bone system—such as large hands, large clavicles, unduly large terminal cartilages of the nose, which are often markedly unsymmetrical on the two sides; or the physical type of the præphthisical is often seen in abundant coarse hair, heavy eyebrows which meet in the mesial line, transverse ridges of the nails; so that, in my experience and recorded observations, the final lung disease is quite a minor part of phthisis, phthisis being a most *general* condition.

I could hardly avoid drawing these illustrations from East Indian diseases, and from European phthisis, of the general character of some of our seemingly most demarked diseases, as suggestive of caution in affirming the "cause" of E. S.'s fatness, and no less as suggestive of caution in affirming the "cause" of her recovery.

One would not dare to affirm that the thymus led to this girl's improvement; she was treated on wide general principles, but the thymus may have justly co-ordinated her inharmonious correlations.

*Slow Progress of Phthisis.*—It is within the knowledge of all practitioners that cases of phthisis have a most varying duration. One sees the bright young girl or youth carried off in a few months, and one no less sees cases running on for years, even to past middle age. It is impossible to state absolutely, the differences of the associated or correlating deviations of structure or function, which belong to, and precede, such different types of cases. Try as one will, it is impossible to state any single or group of differences, either in structure or function, which belong exclusively to either group; and yet the experienced and observant practitioner may often predicate aright, which cases will be rapid and which will be slow in progress.

Of the roses which bloom over the portico, some will fade and die earlier than others; and in young people, the same facts are seen. All may have the bacillus—yet some will rapidly succumb, others will survive for years.

The basis, or greater nature of phthisis, is deep down in the potential and kinetic "energies," and ultimate modes and motions of bioplasm—modes, motions, and ultimate attractions which are of cosmic range and infinite delicacy yet power, and which correlate both with structure

and function, atavically and alternately, often through many generations. Hardly a week passes but that I see the far-back and wide correlations of phthisis, both of structure and function, and I see also their atavism and alternation.

The phenomena are thrust on my observation; I am compelled to state them. I am compelled to see pathology as an orderly series of deviations of the infinite, eternal, and cosmic biological evolution, and as having no less wide correlations in the system.

And as Herschel says, "... a principle may be as completely and as plainly elucidated by the most familiar and simple fact as by the most imposing and uncommon phenomenon," I will cite but three cases in which bacilli were present, and in which the cases were of long duration. This long duration *à fortiori* illustrates how very near to absolute immunity were the patients. One of the cases further illustrates how the patient, ill in phthisis for twenty years, with bacilli known for the past four years, still survives as a bright active woman, whilst in the meantime she has lost two daughters—one at 12 years of age, the other at 20, of phthisis. Where is the potential condition which saves the mother? We must lift our mental view above and beyond the bacillus; we must give up the false but captivating rest in "single causes," in pathology; we must "stoop to conquer," have "humility of pretension," and see biology and pathology in their cosmic relations. Empiricism and the simple observation of Nature may lead us on a right path, long before Science has revealed the exact details.

E. H., female, *æt.* 50, a bright little woman, slight and active; hair wavy and coarse; nose rather pointed; for fifteen years past has had *râles*, and impaired resonance on percussion in the left infra-clavicular region; has had occasional *râles* in right infra-clavicular region. Tubercle bacilli are found. She is thin, but full of life and spirit. One daughter, *æt.* 12, and one, *æt.* 20, have, in the same period, died of phthisis.

The physical signs in her lungs have not progressed during fifteen years. How does her lung-apex bioplasm resist the molecular attractions of the uncelled bacillus? And how did that of her two daughters succumb? I am forced into view of a region of biology and pathology more general and deeper than that mainly confined to the bacillus. We are carried into the presence of "energies," modes of motion, and attractions, absolutely infinite in their correlations, delicacy, and power; the highest physics and vito-physics are involved.

I encouraged, in this case, fresh air; I encouraged her individual psychological tendencies and tastes, also allowed her what food she desired, what her bioplasmic-cell "unconscious memory" longed for, *e.g.*, the allyl modes and motions of the onion.

But the same efforts did not save her two daughters—How not? With her age, the cell-activities and inter-cellular bioplasmic attractions and bonds had, in the processes of the orderly evolution, become stable.

Viewing the phenomena of this mother and her two daughters, one can only say, with Goethe, "Thus, the whole of the throng points to deep-hidden law, points at a sacred riddle!" But bacillus is not the key to that riddle!

A. H., female, *æt.* 34, single, had severe pleurisy of the right side seven years ago. The physical signs of the pleurisy slowly, during two years, cleared off, but bronchial-like moist *râles* were ever present in the right lung. She gradually developed, during three years, well-marked phthisis of the right lung; and during the past year, in a less degree, of the left apex. She has, during the past year, begun to waste, the appetite has failed, and amenorrhœa has existed during the same period.

A. H. has worked up to six months ago in the active duties of a country inn, and has always done her duties well; has lived well. She is a woman of beautiful physical proportions, fine features, beautiful and sound teeth; her bone system is exquisitely fine, such as small, delicately-formed wrists. Tubercle bacilli are found in her sputum. Her system has held on long—six to seven years, but not so successfully as that of E. H., *æt.* 50.

J. M., male, *æt.* 50, came to me for shortness of breath and cough at night. I found slight impairment of resonance on percussion over the left apex, with a few moist *râles*. Tubercle bacilli existed in his sputum. He had lived very much an out-of-door active life, in a most healthy region of West Dartmoor; had drunk malt liquors and spirits freely and habitually. His nails were rather clubbed. Fourteen years ago he "took a chill," and has had cough ever since. Six months ago he took "another chill"; since then, his cough has been worse.

Here, again, as in the two former cases, is slow evolution of the disease, or, as better expressed, there exist "strong molecular bonds" in his lung-apex bioplasm, coincident with, and in correlation with, his age and his entire general system.

For it cannot be too strongly stated that in the widest use of that word phthisis is a *general* condition, and that its major form is *not* in the bacillus.

## MEDICAL ACTS AMENDMENT.

By GEORGE C. CRICHTON, M.D.

It has for some time been proposed to reform the General Council—to amend the Medical Acts.

The amendment on which *at present* most stress is laid is—Increase in the numbers of the direct representatives. Not much is to be hoped for from this, which is to be regarded not as a reform in itself so much as a means to bring about reforms. But which of these is possible in a Council whose only function is examinations, and every ten years a Pharmacopœia? The choice of the constituencies will fall upon the respectable middle-aged or elderly successful doctors; wise and experienced, no doubt, but not greatly daring. How many club doctors, East End doctors—two shillings, or shilling, or so much a week? If one looks through the journals for the last twenty or thirty years, as I have done, one finds repeatedly the accusation that the Council do very little but talk very much. If twenty general practitioners, besides, get on the Council, the effect must be disastrous to business being completed, for what is the use of their being elected if they do not express their views? So that one hesitates as to the value of this reform. When I looked in upon the representative meeting at Oxford, I could not but be struck with the seniority

of the members. Capable and alert, no doubt, otherwise they would not have attained their position there. One stood up, said two sentences, and sat down; then another said a sentence or two, and every second or third speaker proposed an amendment to another amendment to a motion. I soon got lost, and hopelessly. The chairman, however, arranged it all in his mind, and kept all the threads of the debate so completely in hand that he gave his decision when called for clearly and promptly. He looked the youngest of them all, and he is hardly a chicken. As I stood and looked on I saw the *machine* working—smoothly, steadily; but the absence of the note of boyhood touched me as something just a little pathetic. A large infusion of the general practitioner into the Council will, I think, hardly do.

With regard to other reforms, such as registration and finance, the question should at once arise whether every detail should be fixed by Act of Parliament or whether general instructions should be laid down and large powers given to the General Council to make whatsoever arrangements might prove to be the best from time to time? Other reforms, death certificates, foreign and Colonial diplomas, &c., have long waited for settlement. What more reasonable than to empower a duly constituted Medical Council to settle these? Of course, under supervision by a Secretary of State. An annual grant towards the Council's expenses would afford to Parliament an opportunity of discussion, so keeping the Council in touch with the community and Parliament acquainted with the fresh currents of medical knowledge. But this aspect of the case is too large for a short paper.

#### A NEW COUNCIL.

Let us imagine a convulsion of Nature to occur and Parliament to pass an Act reforming the General Council. We should expect that its functions and duties would be *everything* concerning public health, and that it would be in constant communication with the Government of the day as a consultative or advisory committee. It would have the power to issue decrees having the force of law, after obtaining the sanction of Parliament, in the same way as, I believe, the Board of Agriculture and the Board of Education. Practically it would constitute a standing *Committee of Public Safety in Time of Peace*.

It would necessarily be representative.

First. In the first place, instead of being a Committee of Examiners, appointed by every examining board in the Kingdom, there would be representation given to educational authorities, which are, however, also examining boards. It would be the chief business of the Council to supervise education, upon which depends admission to the *Register*, examination being only a test of efficient education. The Universities, then, will each select one representative. (For the present, the new universities in the Midlands, with Durham, would be grouped.) This would give ten or eleven members. It should be decided by the Bill whether the Senatus, as at present, or the General Council (Convocation) of the Universities (as for the representative in Parliament) should elect. The great London medical schools would have a member, elected probably by the staffs of the twelve hospitals. Perhaps the managing committees of these hospitals should elect one of themselves in addition.

Secondly, Direct Representatives. — Every man or woman on the *Register* should have one vote, and the votes should be as nearly as possible of equal value. This is only possible by division into electoral areas or provinces. In England, North, Middle, South, County of London, Wales and Monmouth (5); in Scotland, North-west and South-east (2); in Ireland, North and South (2); in all, 9 members. It is a debatable question whether the corporations should be represented. In a very special and real sense they do represent the profession. They might send three representatives. In England, *e.g.*, the Presidents of the Colleges and the Master of the Apothecaries would in turn elect one member to sit for three years.

The medical element of the Council is now complete. If, however, it is to have large administrative and consultative powers, the general public will be represented. The only practicable way in which this can be accomplished is, I fear, by giving another third of the representation to the President of Council, or other Cabinet Minister. It would be for him annually to appoint two members to serve for five years, ten in all. The Crown members would thus (1) be attached to no political party, and (2) on the occasion of any new question cropping up there would automatically be two vacant places for experts to be appointed to. These appointments should be not as heretofore filled up by fashionable Court physicians and surgeons, but a country doctor, an Army doctor, if you will, but non-medicals chiefly, a barrister or two, some City merchants, perhaps a bishop. A too narrow professional tone should be shunned. Finally, as already said, a grant from the Exchequer would give to Parliament a yearly opportunity of reviewing the proceedings of what would be then, and for the first time, a *General Medical Council*.

Its representatives would consist of:—

- |                      |                   |
|----------------------|-------------------|
| 1. Universities, &c. | 11 to 13 members. |
| 2. Professional ..   | 9 to 12 ..        |
| 3. Government ..     | 10 to 10 ..       |

*i.e.*, from .. 30 to 35 members.

The exact constitution of the Council will obviously depend entirely on its duties, and the purpose for which it is called into existence. Representation *implies* Devolution.

## PULMONARY EMBOLISM,

PROBABLY FOLLOWING THROMBOSIS OF THE HÆMORRHOIDAL VEINS.

By ALFRED S. GUBB, M.D. Paris, M.R.C.S., &c.,  
Of Aix-les-Bains and Algiers.

INSTANCES of pulmonary embolism are sufficiently rare in general practice to render diagnosis a matter of considerable difficulty, especially in the absence of phlebitis or other morbid condition to put the practitioner on his guard. Moreover, in many cases the symptoms at the onset are so vague and ill-defined and withal, so violent that relief of suffering is apt to occupy one's whole attention to the exclusion of pathological problems. Even if one reads up the literature of the subject in the light of a recent case one obtains but little assistance. The various kinds of emboli are duly classified, and they are traced—in the *post-mortem* room—into the ultimate ramifications of the pulmonary artery if indeed their dimensions do not happen to be such as to have caused them to become impacted in one or other of the larger branches. When we turn to the symptomatology one finds nothing absolutely distinctive:

in fact, I am fain to think that in the majority of instances the diagnosis can only be a matter of surmise until the case has run on to its logical conclusion. This being so, a few brief notes of a case that recently came under my notice at Aix-les-Bains may not be devoid of interest.

The patient was an elderly gentleman, a patient of Dr. Cazalis. He had been operated upon a month previously for the removal of troublesome rectal prolapse. Matters had progressed favourably, and at the end of a month the wound had soundly healed and he was authorised to travel to Aix, but he was directed to make daily use of a bougie to overcome any tendency to cicatricial contraction. He had no varicose veins, and was in every respect in perfect health. He took a few baths and felt so well that he was on the point of leaving for his distant home when suddenly, one afternoon, he was seized with intense pain, with a feeling of constriction in the left side of the chest, more marked in front, the pain radiating down the left arm as far as the fingers. The pulse was rapid and the breathing shallow and somewhat gasping. At first sight it looked like a typical case of angina pectoris, and a dose of ether, followed by the hypodermic injection of morphine, afforded a great measure of relief. The dyspnoea, however, persisted on the following day and on auscultation a patch of fine rales was made out just to the left of the sternum, behind the fourth and fifth costal cartilages. The pulse was still rapid and small, the heart sounds were distant and muffled, and they were masked by the rales, which were attributed to pericardial friction. The temperature was normal. The tongue was very thickly furred and there was complete anorexia with occasional attacks of nausea, and even actual vomiting after taking food.

In view of the intensity and obscurity of the symptoms the patient was kept under close observation, and it was at this juncture that Dr. Cazalis asked me to assist him in the management of the case. A blister was applied over the base of the heart, followed by poultices, with occasional injections of morphia, but although we were successful in relieving the pain and dyspnoea to some extent, the patient's condition in no wise improved. On the morning of the second day after the onset of the attack dulness and crepitation appeared in the front of the right lung, and on the following day, April 26th, the patient, who so far had not been troubled by cough, began to expectorate sputum containing bright red blood, frothy and mixed with viscid mucus. There was nowhere any bronchial breathing and the temperature remained normal. On reviewing the symptoms we came to the conclusion that it was probably a case of pulmonary embolism, although we were at a loss to account for its occurrence, the possibility of its having any etiological connection with the operation on the rectum six weeks previously appearing rather remote.

Advantage was taken of the presence in Aix of Professor Chantemesse, of Paris, to obtain the benefit of his experience. He confirmed the view that the case was probably one of pulmonary embolism, presenting the unusual feature that the left lung was the first to be involved. In the absence of any other plausible explanation of the origin of the embolism he was inclined to incriminate a thrombosis of the hæmorrhoidal veins, consecutive to the operation. Possibly the introduction of the bougie had displaced part of the clot, which had thus found its way into the circulation. Inasmuch as clots in that situation would in all probability be infected, he took a grave view of the case.

The congestion, with the accompanying rales in the left lung in front, interfered greatly with auscultation of the heart, but the small, rapid and sometimes unequal pulse testified to the existence of profound cardiac disturbance. Digitalin (Nativelle) was prescribed for the purpose of reinforcing cardiac action, but the result did not fulfil our expectations.

During the next few days the patient's condition varied, there were temporary improvements followed by fresh outbursts of congestion, both in front and at the bases, and increased dyspnoea, and on each occasion the

sputum which, from bright red had become rusty, again contained fresh blood. The temperature oscillated about normal, and the pulse, rapid and small, varied between 110 and 130 per minute.

On the tenth day of the illness the urine became scanty and contained a trace of albumin. The patient became subject to violent attacks of spasmodic dyspnoea, which distressed him greatly, especially at night. These attacks presented a close resemblance to asthma, and were assuaged by morphine, dry and wet cupping and stramonium inhalations. In the course of the next few days the urinary secretion fell to about a pint in the twenty-four hours, in fact, it was obvious that the pulmonary condition was complicated by uræmia. The pulse became very weak and at times almost imperceptible, and at intervals copious cold sweats broke out. He rallied for a time under injections of spartein and caffeine, but his speech soon became incoherent and he lapsed into a state of coma, in which he died in spite of inhalations of oxygen and stimulants.

No *post-mortem* examination was obtainable, but the history of the case, the repeated formation of rounded areas of pulmonary congestion, the expectoration of bright red and then brown sputum, followed by further expectoration of bright blood consequent upon fresh areas of congestion, the absence of marked febrile reaction, and finally the toxic uræmia that closed the scene all point to pulmonary embolism as the result of a disintegrating clot somewhere in the venous system, the source of the mischief being in all probability in the hæmorrhoidal veins.

## Transactions of Societies.

### CLINICAL SOCIETY OF LONDON.

MEETING HELD DECEMBER 9TH, 1904.

The President, DR. FREDERICK TAYLOR, in the Chair.

#### THE TREATMENT OF INTUSSUSCEPTION IN CHILDREN.

MR. CUTHBERT S. WALLACE read a paper on a series of cases of intussusceptions in children treated at St. Thomas's Hospital and the East London Hospital for Children between the years 1898 and 1904. There were 20 cases in all, the ages varying between three months and thirty-three months. There were 12 males and 8 females. Of the twenty cases 19 involved both the small and the large gut; the remaining case was one of the colic variety. Eleven were single tumours and 9 were double. The author agreed with Mr. Edred M. Corner that the double tumours were more common than supposed, and he referred to the difficulty that was encountered if a complete nomenclatural classification were attempted. The diagnosis was clinched by the finding of a tumour, and if there were any doubt of the presence of a tumour an anæsthetic should be given and the matter settled at once. The treatment was primary celiotomy, the most convenient incision being through the right rectus beside the umbilicus. The author did not lay any great stress on the reduction of the tumour within the abdomen, but thought that time was the most important element in the treatment. The after history of the cases seemed to show that as far as the ultimate result was concerned the method of suture of the belly wall was immaterial. The method favoured was by deep sutures through the whole thickness, and buried sutures through the sheath of the anterior rectus. By this method the danger of the incision coming open from failure of union was reduced as far as possible. Of the twenty cases four died, giving a case mortality of 20 per cent. If the two cases of resection were excluded the case mortality fell to 11.11 per cent. The author finally referred to the great fall in the case mortality that had taken place of late years. Statistics drawn from the records of St. Thomas's Hospital showed that there was a marked increase in the number of cases of intussusception admitted to hospital.

#### ON THE TREATMENT OF INTUSSUSCEPTION IN CHILDREN BY LAPAROTOMY.

Mr. C. H. FAGGE read a paper based on the results of

18 laparotomies, of which 17 were primary and one was undertaken after two attempts at reduction by inflation had failed. In 16 a tumour was discovered either in the abdomen or *per rectum*; both the other two cases ended fatally; in the first no surgeon was called in for twenty-four hours and though reduction was easy, the patient, *æt.* 9, died on the fourth day; in the second, a boy, *æt.* 15, the intussusception of the enteric type, was irreducible, and was resected. He drew attention to the variable position occupied by the tumour and insisted on the importance of routine rectal and bimanual examination, if necessary under an anæsthetic, as aids in coming to a prompt diagnosis. Duration before operation varied from five hours to three weeks, and though there was no direct relation between this and ease of reducibility, he pointed out that no case in which the duration was less than forty-eight hours had been irreducible. Eleven were single and seven double intussusceptions, of which at least 10 were ileo-cæcal, and 3 colic ileo-cæcal; he did not regard a minute division of intussusceptions as of much clinical value; probably 8 of his cases would not have been, owing to their origin above the ileo-cæcal valve, in any way affected by inflation or irrigation. Reduction was by laparotomy, carried out with all possible speed through an incision usually in the right semilunar line, and this was aided if necessary by an assistant's finger in the rectum, which reduced the intussusception well into the descending colon. Five cases were irreducible and all were fatal; in one an artificial anus was formed, and in all the others resection was performed and the ends of the bowel united, in one by Maunsell's method, and in the other three by simple end-to-end anastomosis with two rows of sutures, the inner passing through all the coats and the outer through the muscular and peritoneal coats. Of the 18 cases 7 died, giving a mortality of 39 per cent.; of the reducible cases (13 in all) 2 died, a mortality of 15.4 per cent.; in the 14 cases under one year the mortality was 21.4 per cent., or, excluding the two which were irreducible, there was only one death, giving a mortality of 8.3 per cent.

Mr. ARTHUR BARKER remarked on the large number of double intussusceptions recorded by the authors. He had never seen a case of this nature, although he had operated on over thirty cases. He agreed with Mr. Fagge that escape of the bowel from the abdomen was a most undesirable complication of the operation, as it lengthened the time occupied, and added to the shock. He differed from both authors as to the length of incision necessary, and thought it was rarely advisable to make one over two inches long. He attributed the cases just described of bursting open of the wound to this factor, as he has never seen such an occurrence in his cases. In this connection he believed it was important to conduct the first dressing under opium and chloroform. He was very interested in the question of toxæmia, and had several times noted a rise of temperature on the following day to 105° F., and even to 107°, there being no diarrhoea, distension, or other symptom. He was very pessimistic about the gangrenous cases, as he had never had recovery after resection in such cases, and never expected to see one. The only hope lay in earlier operation.

Dr. CHAS. BOX referred to the medical aspect of the subject and upheld the custom of admitting all acute abdominal cases first under a physician. He believed that the danger of a double administration of chloroform, first for diagnostic purposes and then for treatment, was counterbalanced by the gain in knowledge attained when dealing with cases of doubtful enteritis with melæna. He discussed the diagnosis and mentioned a case of Riedel's lobe of the liver, thought to be of congenital origin, which gave rise to difficulty. He did not think that any additional shock arose from the escape of intestines from the wound, while this was often an indispensable aid to the operator. He considered that the occasional bursting open of the wound resulted from non-union, due to toxæmia, and instanced the analogous cases of non-union after operation on perforated typhoid ulcers.

Mr. DOUGLAS DREW had operated on thirteen cases. Two gangrenous cases died, and one other. This latter had a temperature of 106° on the following day, and died of toxæmia. This case was one of double intussusception, the only one he had ever seen. He, like Mr. Barker, reduced within the abdomen, but always withdrew the cæcum so as to examine it. In several of his cases the caput coli was the most difficult position to reduce. He had never seen a wound burst open.

Dr. BROOK asked whether inflation was ever justifiable. He had performed it with success. He also would like to know what treatment Mr. Wallace recommended for the irreducible cases, whether splitting of the outer layer or resection.

Mr. WALTER SPENCER speculated as to the cause of the toxæmia. It might arise from the intestinal lumen from the strangulated vessels, or from the peritoneal cavity. Could anything be done for the condition, say by stimulating peritoneal phagocytosis?

Mr. JAMES BERRY had seen forty or fifty cases operated on. He had never heard of a successful resection under the age of two, and doubted its justifiability. That being so, it was correct to use force in persisting in the attempt to reduce difficult cases.

Mr. MCGAVIN asked how often relapses occurred after laparotomy, as compared with relapses after inflation.

Dr. TAYLOR pleaded guilty to having assisted at inflation, and had even recorded successful cases before this Society.

Mr. WALLACE, in reply, said that his unusual number of double intussusceptions was probably due to chance, though it had been suggested that many such cases dealt with intra-abdominally were overlooked. The length of incision was a personal preference, it being impossible for some operators to work through a small orifice. He was convinced that the bursting open of wounds was not due to long incisions, as it occurred when these were only one inch long, but was probably due to toxæmia. He thought that inflation should never be done, as no one could ever tell whether complete reduction had taken place, the disappearance of the tumour might only mean that the intussusception was tucked away behind a flexure or under the liver. He, like Mr. Berry, had never heard of a case of successful resection under the age of two, so that forcible manipulation was the only thing to do. In certain cases, such as those with a prolapse of the ileum through the ileo-cæcal valve, actual pulling was indicated as well as the usual pushing and squeezing. He had never seen a recurrence after operation.

Mr. FAGGE, in reply, also thought that double intussusceptions were often missed, but, as laparotomy was always indicated, their importance need not be insisted on. He never made an incision under three inches long, even in a small child. He regarded the onset of toxæmic symptoms, such as a temperature of 103° or 104°, as of favourable import. He had only seen one case of recurrence after operation, but many after inflation.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF SURGERY.

MEETING HELD IN THE ROYAL COLLEGE OF SURGEONS  
ON FRIDAY, DECEMBER 2ND.

The President, Mr. ARTHUR CHANCE, in the Chair.

#### EXHIBITS.

Mr. R. C. B. MAUNSELL exhibited a child after operation for spina bifida, also the meningocele which he had removed.

Mr. KENNEDY exhibited (a) Infant operated on for intussusception; and (b) child treated for hydrocephalus by repeated lumbar puncture.

Mr. BLAYNEY exhibited a Gasserian ganglion removed for epileptiform neuralgia.

Mr. W. TAYLOR exhibited (a) Gall-bladder removed

for gangrenous cholecystitis; and (b) hydronephrotic kidney.

Mr. EDWARD H. TAYLOR read a paper entitled **A NEW METHOD OF PROCEDURE FOR THE RADICAL CURE OF INGUINAL AND FEMORAL HERNIÆ**, and illustrated its various stages by means of lantern slides. Having introduced the subject by some general remarks concerning the anatomy of the inguinal canal and the aims of herniotomy, he proceeded to explain his method of operation. With the patient in the Trendelenberg position, a vertical incision about four inches in length is made midway between the middle line and the outer border of the rectus muscle in its lower part. The superficial tissues and the rectus sheath having been divided, the outer lip of the divided sheath is raised and the corresponding border of the muscle defined and drawn inwards. The transversalis fascia is then divided and the extraperitoneal fat exposed. The next step consists in fully retracting the outer margin of the wound towards Poupart's ligament, and identifying the neck of the hernia. By seizing the parietal peritoneum close up to the internal abdominal ring with the finger and thumb, the sac is drawn up to some extent out of the inguinal canal and opened, after which a finger is introduced into its interior to act as a guide while it is being separated from the structures of the cord. A ligature or purse-string suture is then applied to the neck of the sac, and the fundus cut away. The inguinal canal and the two rings are now explored by the finger, the structures of the cord are identified, and the deep epigastric vessels held aside. By means of special needles in handles—modifications of the ordinary aneurysm needle with a slot at one side opening into the eye—a series of silk sutures (No. 6 size) are passed so as to connect the conjoined tendon and the transversalis muscle with Poupart's ligament, just enough space being left to allow the structures of the cord to pass without being unduly compressed. The rectus muscle now resumes its normal position, but for greater security its outer border is connected to the deep aspect of the transversalis muscle by a few interrupted sutures. Finally, the rectus sheath is closed in front by interrupted sutures also, and the skin margins approximated by a continuous subcuticular suture of silkworm-gut. Should the external abdominal ring be unduly patulous it may be readily exposed before closing the wound by drawing aside or reflecting the overlying tissues, and its dimensions reduced by one or two sutures. In the case of femoral hernia the steps of the operation corresponded to the above up to the point at which the femoral ring is exposed. The sac is isolated as already described, ligatured at its neck, and its fundus cut away. The closure of the femoral ring is then effected. Two sutures generally suffice for this purpose. Each passes through the conjoined tendon and Poupart's ligament in front, beneath Cooper's ligament behind. In some cases it is advisable to pass them through two holes previously drilled in the pubic bone. Mr. Taylor pointed out that a somewhat similar method for occluding the femoral ring had been described by Mr. Mayo Robson in the "Year-Book of Treatment" (1904), but, nevertheless, it differed from his in certain important particulars.

Mr. JAMESON JOHNSTON expressed himself in favour of Bassini's operation, as he considered it the simplest, most scientific, and the easiest. He regarded the objection to dividing the aponeurosis of the external oblique in this operation as more or less theoretical. Mr. Taylor's operation would probably be a good one in old herniæ, in which the internal abdominal ring approached the middle line.

Mr. T. E. GORDON considered there was no one method of operation for hernia. Mr. Taylor's method was not suitable in the case of a congenital hernia in a young child. He believed there were many of the operations practised which were hopeful as regarded ultimate success. The essential thing in these operations was asepsis.

Sir THOMAS MYLES referred to the valve-like nature of the inguinal canal. So long as its anterior and

posterior walls remained in contact and the muscles sufficiently tense a hernia was unable to push these walls apart. He thought there was a hereditary predisposition to hernia. The valve-like closure of the canal, due to muscular action, was essential, and that being so, no amount of suturing of the conjoined tendon to Poupart's ligament would provide an obstacle to recurrence, because sufficient space had to be left to permit the cord to pass.

Mr. BLAYNEY was of opinion that the weakness of the abdominal wall in the inguinal region was for a special purpose, *vis.*, to allow the thin fascia transversalis being pushed against the external oblique when the intra-abdominal pressure was increased.

Mr. TAYLOR, in reply, stated that he believed his method of operation was best suited for large, well-developed inguinal herniæ, in which the inguinal canal had undergone marked changes in size and direction. As bearing upon the success of the procedure he thought it of importance to mention that the sutures in the conjoined tendon should not be tied too tightly, and that the parts should be kept at rest for a sufficient time afterwards to permit of healing taking place. Patients were frequently allowed to get about too soon after herniotomy; absolute rest for at least a fortnight was desirable. As to the mode of development of an inguinal hernia, he thought it probable that there was in many instances a degree of congenital weakness at the internal abdominal ring, in consequence of which the latter went on increasing in size. There was such a thing as a hernial type of abdomen, and it was in such cases that weakness or dilatation at the internal abdominal ring was most likely to be found. Upon the hernia commencing to develop, the conjoined tendon and the fascia transversalis yielded more and more, and the inguinal passage became progressively larger, and less oblique in its direction.

Mr. T. E. GORDON read an account of a case of ACUTE INTESTINAL OBSTRUCTION FROM A GALL-STONE.

The patient, æt. 73, had had an attack of biliary colic in February, and she did not recover fully from this for two months. On August 6th, she was seized with intense pain in the liver region, and this was followed by complete obstruction of the bowels. Three stages in the course of the illness were clearly defined: (1) A stage of onset lasting from August 6th to August 7th, marked by intense epigastric pain and vomiting, but without fever; (2) a stage of quiescence lasting until August 9th; (3) a stage with unequivocal signs of intestinal obstruction. The operation was performed by Mr. Gordon on August 11th. A gall-stone was found firmly impacted in the upper part of the jejunum. After the operation all vomiting ceased, and the patient was able to leave her bed in about a fortnight. Mr. Gordon, in attempting to interpret the clinical signs, said he thought it probable that impaction did not occur prior to the third stage. It was difficult to understand why a stone of such small size should cause intestinal obstruction. Spasm was obviously an important factor.

Mr. W. TAYLOR stated that he had seen the patient a few days before Mr. Gordon performed the operation and on the day before he left town for his holiday. She was then under the influence of opium. He thought that at that time, the gall-stone made its exit from the bile passages. At the same time, however, he had not overlooked the possibility of intestinal obstruction. He would like to know if any reasonable explanation could be offered why a calculus of this size should become impacted.

Sir THOMAS MYLES alluded to a case in which he had removed a large impacted gall-stone, fifteen years ago. He thought it likely that the impaction in the present case was due to the opium administered, the muscular tissue of the bowel being paralysed. He would advise in such cases that the incision into the intestine be made not directly over the gall-stone, but on the proximal side, as otherwise one cut through infiltrated and devitalised tissues.

Mr. JAMESON JOHNSTON inquired as to the amount of distension present and the condition of the bowel

at the site of impaction. Mr. Gordon alluded to spasm but he did not think spasm could exist under the conditions present, *viz.*, inflammatory infiltration and oedema of the bowel wall.

Mr. BLAYNEY thought the impaction of the gall-stone in the present case might be due to its rough exterior, by which the mucous membrane of the intestine was irritated and abraded, thus permitting micro-organisms to act. This resulted in oedema of the sub-mucous tissue which extended inwards rather than outwards. He believed the impaction was due more to inflammatory oedema than to spasm.

Mr. GORDON, in reply, said he thought some of the suggestions which had been made as to the cause of the impaction were correct, but that he himself had none to offer. The abdominal distension was not very great. He made the parietal incision above the umbilicus, because the early pain complained of was referred to the upper part of the abdomen.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DECEMBER 1ST, 1904.

DR. JAMES BARR, the President, in the Chair.

DR. GROSSMANN showed a patient with Conical Cornea, and demonstrated the skiascopic appearances, which were particularly striking in this case owing to the high degree of the deformity, its centrally situated apex, its complete transparency, and the easy comparison with the other unaffected eye.

Dr. W. B. WARRINGTON read a note on the Plantar Reflexes. He described the plantar reflex of the normal flexor type and the pathological extensor response. He emphasised the importance in the method adopted for obtaining it, and considered that only to the slow, deliberate extension could a certain pathological significance be attached, though other types of extension might be very significant. The reflex obtained in various diseases of the nervous system was described, and it was maintained that the character of the reflex was a valuable aid in distinguishing between functional and organic disease, and equally so in differentiating between the different kinds of organic nervous disease.

Dr. T. R. Glynn, Dr. R. J. M. Buchanan and Dr. J. Hill Abram took part in the discussion.

Dr. W. ALEXANDER exhibited a Dumb-bell Calculus he had removed from a man, *æt.* 43. The calculus had existed for some years, and a rigorous administration of solvents had no influence upon it. Suprapubic lithotomy was performed, a stone removed, and the wound closed. It was then found that another stone remained behind the prostate; this was removed by median lithotomy. The two stones thus removed formed a dumb-bell calculus. The bladder was divided into two cavities with a constriction between. It was found impossible to distend the bladder with lotion preparatory to the suprapubic lithotomy, as when the small sac was filled contractions occurred and the urine was expelled with force alongside the catheter. Dr. Alexander said the case was unique in his experience, but Mr. Poland, in "Guy's Hospital Reports" for 1857, described a nearly similar case and discussed the mode of formation of such calculi.

Mr. RUSHTON PARKER said that the first perineal section performed by him, now many years ago, on a boy, *æt.* about 11, gave a dumb-bell calculus, one portion of which lay in a sac by the prostate, and the other in the bladder.

Dr. C. J. MACALISTER read a paper on "Some Thoughts and Suggestions Concerning Gastric Ulcer." He pointed out the fact that the characters of the ulcers are peculiar, both as to their shape, the course which they run, and their surroundings, and commented upon the unsatisfactory explanations which have been given heretofore concerning the cause of the disease. By a series of lantern slides he demonstrated the characters of the simple gastric ulcer in its uncomplicated condition, as distinguished from the same ulcer when secondary inflammations had taken place, and he also gave illustrations of other types of ulceration, and

pointed out that these did not tend to be converted into the so-called simple perforating ulcer. In seeking for a cause of the condition, it was obvious that the disease mainly attacked women; and from a study of the sequence of events connected with the development of the thyroid, the association of amenorrhœa and of concomitant indications of vaso-motor spasm, followed by the chlorosis and stomach disorder, he suggested that the disease was another instance of vaso-motor spasm followed by necrosis dependent upon a toxæmia. He thought this the more probable since the administration of thyroid extracts frequently relieved the amenorrhœa, and that following this there was sometimes great general improvement in the health of the patients. Dr. Macalister was emphatic concerning the necessity for taking the cases in hand during the early stages, and that whatever might be done in the way of thyroid treatment later in the disease, it was necessary to use all the usual precautions as regards rest, diet, and palliative treatment in addition.

The President, Dr. E. T. Davies, Mr. E. M. Stockdale, Dr. W. Carter, Dr. T. R. Glynn, Dr. T. R. Bradshaw, Dr. J. Hill Abram, Dr. E. E. Glynn, and Dr. R. J. Logan took part in the discussion.

A resolution congratulating Mr. E. R. Bickersteth on having attained his jubilee of membership was proposed by the President, seconded by Mr. Rushton Parker, and carried with acclamation.

#### LARYNGOLOGICAL SOCIETY OF LONDON.

MEETING HELD DECEMBER 3RD, 1904.

DR. LAW showed a case of incrustations in the trachea, which had been shown at the former meeting. The patient suffered from considerable dyspnoea, and the question was raised as to whether tracheotomy might not be necessary. Dr. Bronner showed some crusts from a case of dry catarrh of the nose and nasopharynx which had been treated by formalin spray. An interesting case of epithelioma of the larynx was shown by Sir Felix Semon. Thyrotomy had been performed but was followed by fairly rapid recurrence. Subsequently a great part of the affected half of the larynx was removed, and the man made an excellent recovery. The striking part of the case was the extraordinarily good voice left. An apparently almost unique case of a bony growth in the ethmoidal region of the nose in a girl was shown by Dr. Lambert Lack. There was obstruction of the maxillary osteum from the growth, and mucocele of the antrum. The diagnosis microscopically suggested was ossifying sarcoma. Two cases were shown of tumours in the neighbourhood of the tonsil; one by Dr. Wyatt Wingrave, in a female, *æt.* 64, and the second by Dr. Tilley, in a young man. In Dr. Tilley's case there were a large number of enlarged cervical glands, and in both cases the diagnosis was that of a lympho-sarcoma. In Dr. Tilley's case the glands and the enlargement of the tonsil had almost entirely disappeared under the influence of large doses of arsenic. An interesting case of chronic laryngitis in a man, *æt.* 32, was shown by Dr. Cathcart. The general opinion of members was that the condition was one of extreme pachydermia. Mr. F. J. Steward showed a case of complete paralysis of the left vocal cord, due to a tumour of the thyroid. The clinical aspects of the tumour were those of non-malignancy, but the case was shown with the view to eliciting opinions as to the question of malignancy.

#### ULSTER MEDICAL SOCIETY.

MEETING HELD IN THE MEDICAL INSTITUTE, BELFAST.  
DECEMBER 8TH, 1904.

DR. JOHN CAMPBELL, in the absence of the President, in the Chair.

THE following gentlemen were elected Fellows of the Society:—Drs. D. C. Kirkhope, S. Macauley, and J. H. Lowry, all of Belfast; and the following as Members: Drs. S. T. Irwin and S. Blakeley, of

Belfast ; J. M'Clatchey, of Dumurry ; and J. McArthur, of Grey Abbey.

Mr. ROBERT CAMPBELL, F.R.C.S., read a paper on SOME INJURIES TO JOINTS.

Dealing with those of the lower end of the humerus, he said that all fractures should be put up in the acutely flexed position, except those in which there was displacement of fragments of the bone. Fractures of the head of the radius he found most often as the result of bicycle accidents, the rider getting a side-slip and lighting on the palm of the hand. The fracture generally ran in an antero-posterior direction down the head of the bone, tailing off to the inner side. The fragment of bone was often broken into two pieces. The signs of this fracture might be slight : simply swelling and tenderness over the head, but on pronating and supinating the hand to an extreme degree one could get crepitus over the head. If such a fracture were left alone the callus would eventually interfere with movement, and the best treatment was to cut down on the head of the bone and remove it, the results being good. Fractures of the carpal bones were frequently seen in hospital as cases of "sprained wrist" that had never been treated, or which had not recovered under treatment. They showed thickening and tenderness over the carpus. These fractures were due to a fall, not a crush. The diagnosis could only be made by a careful palpation of each row of carpal bones ; tenderness will be found at both back and front of one bone. Radiography is most useful in confirming one's diagnosis in these cases. Fracture of the base of the first metacarpal bone is due to force applied to the end of the thumb, and is discovered by the tenderness on pressure in that direction. The diagnosis is difficult unless one gets a history of violence applied in this direction, and may only be possible by radiography. Dislocations of the semilunar cartilages of the knee-joint are often described as being outwards, but in the large number of cases which Mr. Campbell had seen in the Royal Victoria Hospital extern he had never seen one outwards. He had operated on seven, and in all but one the displaced cartilage was lying between the condyles of the femur. He considered the only really satisfactory treatment was removal. If his observation as to the direction of displacement was correct, it showed the absolute futility of all special pads and such things.

The paper was discussed by Drs. O'NEILL, FULLERTON, MITCHELL, MOORE, ST. GEORGE, and O'CONNELL, several of whom expressed strong dissent from the views set forth in the paper.

Mr. ANDREW FULLERTON, F.R.C.S.I., showed skiagrams of (a) fracture and dislocation of the astragalus, and (b) dislocation of the scaphoid and fracture of the carpal bones.

Mr. A. B. MITCHELL, F.R.C.S.I., read a paper on some INEFFICIENT GASTRIC OPERATIONS, giving an account of six operations in which the hoped-for relief had not been obtained, or had been only temporary. The paper was virtually a continuation of one read last session, giving an account of a large number of operations for the relief of gastric ulcer and the conditions arising therefrom. The paper was discussed by Messrs. Kirk, Fullerton, and Robert Campbell.

PARIS, December 12th, 1904.

### EPIGASTRIC PAIN IN NEURASTHENIA.

THIS symptom, common enough in general practice, is frequently misunderstood by the practitioner. It may be classed with the painful form of dyspepsia where there exists hyperæsthesia of the mucous membrane.

The patient is generally a woman. She complains of pain in the stomach coming on after eating. Sometimes a sensation of burning exists, with acid regur-

gitation. The case is supposed to be one of hyper-acidity of the stomach, which, in fact, often co-exists, but not constantly, or that of ulcer. The patient is ordered milk diet, absorbent powders, and warm drinks, but with no result ; the suffering continues. After a time the patient throws aside the régime and eats as usual, and is surprised to find that the food passes without any inconvenience, except spiced food and wine. M. Page published lately several cases where the above symptom was the most prominent, and came to the conclusion that such patients are of the neurasthenic class, in whom the epigastric pain is provoked by different causes—emotion, food, monthly periods, &c. The pain is very violent, and has two points of election : three fingers' breadth from the xiphoid cartilage in front and the eighth dorsal vertebra behind, and is due to neuralgia of the solar plexus. Certain organs, as the uterus and kidneys, being in the territory of this nerve system, should be examined with care, and by treating the affections of these organs (metritis, floating kidney, anteversion, &c.), the epigastric pain would be cured. But frequently no cause can be discovered.

M. Page recommends faradisation of the stomach.

### TREATMENT OF EXOPHTHALMIC GOITRE.

AMONG the agents employed in the treatment of exophthalmic goitre, there is one which was recommended some years ago by a provincial physician, and although others tried it with considerable success, that treatment has fallen more or less into oblivion. However, quite recently Dr. Joussemet took this subject for his thesis and published eighteen cases of exophthalmic goitre treated by this method, with unvaried success. M. Joussemet does not believe that every case is amenable to salicylate of soda. For him, it is the pure form, with or without goitre, with neuro-arthritis as predisposing cause, emotion for determining cause, and phenomena due to the functional hyper-activity of the cells of the sympathetic system for symptoms, that this agent acts almost as a specific.

The dose is generally fifteen grains three times a day, but larger doses may be given if well borne by the patient. To avoid irritating the stomach, however, it is good treatment to give it in milk or in Vichy water.

The treatment must be continued for weeks, months, and even a year, with a few days' interruption every month.

### TREATMENT OF SENILE GANGRENE.

The treatment varies according to the period of the disease. At the beginning, when the condition of the threatened region can be improved, recourse will be had to vaso-dilators or cardiac tonics, rest in bed with the limb bound in dry cotton wool to encourage the circulation in the affected parts, and as a therapeutic agent :

Iodide of potassium, 1 dr. ;

Water, 10 oz.

A tablespoonful twice a day.

At the same time theobromine, an admirable diuretic eliminating the toxins of the blood, and a cardiac tonic, will be given in the daily dose of ten grains.

After twenty days of this treatment, trinitrin will be ordered for the last ten days of the month :

Solution of trinitrin 1-100, 40 min. ;

Sulphate of spartein, 15 grs. ;

Water, 12 oz. ;

Three dessert-spoonfuls daily ;

or

Nitrite of soda, 30 grs. ;

Bicarb. of soda, 2½ drs. ;

Nitrate of potash, 2½ drs. ;

Water, 10 oz. ;

Three dessert-spoonfuls daily.

Once the gangrene has set in, the above treatment can be continued, and local antiseptic treatment instituted. According to Dr. Huchard, lotions with permanganate of potash solutions (1-1,000) followed by the permanent application of compresses wet with oxygen water, recently prepared, is the best. Some

patients, however, prefer the dry treatment. In such cases, after cleaning the parts with oxygen water, peroxide of zinc gauze is applied.

### Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 10th, 1904.

At the last meeting of the Gesellschaft der Aertze Hr. Bumm spoke on  
LIGATURE OF THE EFFERENT UTERINE VESSELS FOR  
PYÆMIA.

Four years ago, Freund proposed ligature of the vessels going from the uterus in cases of pyæmia proceeding from that organ, as they frequently contained suppurating thrombi. Freund had had a recovery, but he had not. Trendelenberg ligatures the hypogastric veins without touching the spermatic in one case, and with a good result. The latter operation also led to a good result in the hands of Michaelis. The speaker now brought forward the two first cases of recovery from chronic pyæmia after ligature of the hypogastric veins. In the first case peritonitis set in soon after delivery; the patient recovered from this by drainage. Then rigors took place. He ligatured the spermatic before the hypogastric. The ligatures sufficed to completely arrest the circulation in the veins of the pelvis; double ligature and excision would only have given a fresh occasion to renewed infection. As the veins were still there after the operation there might still be a few rigors of no importance. In the second case, the pyæmia followed delivery by forceps. Whilst Trendelenberg operated extra-peritoneally, he proposed to operate from the peritoneum, as the desired result was obtained more quickly. One must bear in mind not to ligature the ureter, which ran near to the vein.

Hr. Stoeckel related a case of  
GANGRENOUS CYSTITIS

in a woman (with cystoscopic demonstration). In a case of sepsis following forceps delivery, recovery was delayed by an attack of gangrenous cystitis. Such a cystitis might cause a patchy or a more extensive superficial destruction of the bladder wall. The pain accompanying the affection resembled that of labour. The destruction was not total, as was formerly believed, so that attachments to bowels helped to form a container for the urine, but the bladder was retained *in toto*, the shelled-off part only reaching to the middle muscular layer, the part where the circular muscles lay around the orifices of the ureters. The result was insufficiency of all the openings, through loss of the controlling muscles. Thus in the case before them (demonstration) the openings of the ureters were not small flat slits, but crater-like, gaping depressions. This loss of closing power was the cause of the increased danger of ascending suppuration.

At the Society für innere Medizin, Hr. Senator spoke on

PHYSIOLOGICAL AND PATHOLOGICAL ALBUMINURIA.

Up to modern times, albumin in the urine was always looked upon as pathological. He himself, in 1882, had shown that traces of albumin were sometimes met with in healthy urine. Later on it was shown that the albumin was a sero-albumin, and that it could only be discovered by delicate methods. In other more recent times, a real albuminuria had been observed in persons who showed no symptoms of disease, at any rate they had no kidney disease. This had been called functional or idiopathic albuminuria, and it was a question whether the symptom was a pathological or a physiological one. Leube had shown in 1878 that after heavy marches soldiers not infrequently had albumin in their urine. The idea, however, could not be rooted out that normal urine was free from albumin, and this arose from a misunderstanding or mixing up of the terms abnormal and pathological, and there were many abnormalities that were not pathological. There was a so-called physiological glycosuria, and a physiological

acetonuria, &c. It was, therefore, not strange that after violent exercises such as football, &c., or after a hearty meal, there should be some albumin in the urine. Rapp found albumin in cadets in 1.7 per cent. of the cases. Menstruation caused albuminuria in many women, and cold baths also, and albuminuria was pathological when it appeared under normal conditions, and not when it occurred under certain conditions and disappeared when the special condition ceased.

Another kind was the cyclic or orthotic, which occurred in children when they were moved from a horizontal to an upright position, but this was certainly pathological. In all these forms the albumin hardly ever exceeded  $\frac{1}{2}$  per cent. As regarded cold baths, the blood film was altered by cold baths; a leucocytosis developed in the blood stream, and these multinuclear leucocytes could exert an influence on the kidney. Rosenbach had made the interesting observation that in periodic hæmoglobinuria albumin was present in the urine even at the commencement of an attack; even in incomplete attacks from cold there was always albumin in the urine. Under such circumstances the albumin was pathological. Of the causes of albuminuria in menstruation he knew nothing.

After copious meals the circulatory condition played a part. Possibly the flow of blood from the kidney was hindered by distension of the abdomen, or there might be open communication between the portal vein and the general venous system. In the normal condition such communication might remain open, so that albumin might get into the circulation without going through the liver at all.

### Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 10th, 1904.

HEPATIC RUPTURE.

At the Gesellschaft der Aertze, Schnitzler presented a drayman on whom he had operated for rupture of the liver. Nine hours after being crushed by a cask of beer, the patient was brought to hospital in a very anæmic condition, the abdomen greatly distended, both flanks dull on percussion, while the hepatic dulness was normal. A tear of the mesentery was diagnosed, and laparotomy decided upon as an immediate operation.

On opening the abdomen a large rent in the liver presented itself, the mesentery between the stomach and liver being torn. Two litres of blood were removed. The rupture was located in the lower and posterior margin of the left lobe, in which a man's fist might be placed. As stitches in this position were almost impossible, the hæmorrhage was checked by temporising with a weak solution of adrenalectin, conducted through the upper angle of the abdominal wound.

The case is interesting from the sequelæ, as embolism of the left lung speedily followed the recovery from the accident. At the present time infiltration and shrinkage of the lung still exist. The morbid changes are likely to have arisen from primary embolism of the hepatic cells, from which fragments were carried along the pulmonary artery to the lung, where the destruction took place. Schnitzler thought as far as the wound of the liver was concerned it would heal itself without much trouble, but the danger lay in the stypic.

Here he read a published case of hepatic rupture where no operation was performed, which nine months after the accident discharged in the form of a subphrenic abscess, large sequestra of liver being found in the purulent matter.

Lotheissen had another case to show the members where the tear in the liver was more superficial than either of the two cases previously described. The patient had been engaged in removing benzine when one of the casks exploded, throwing him violently to the ground on the abdomen, rupturing the liver. When

received into hospital he was anæmic, abdomen tense and painful, especially over the umbilical region. Both flanks were slightly dull, and no blood in the urine. Five hours after the accident he was operated upon, and about two litres of blood taken out of the abdomen. It was then discovered that the left lobe of the liver was torn, leaving a rent that would hide a good-sized apple. A portion was hanging by a pedicle, as thick as the finger. Four stitches were applied, over which was placed a pad of iodoform gauze, while the pedicle was removed by the Paquelin to prevent hæmorrhage, and finally a tampon of gauze placed between the stomach and liver, which was ultimately removed by the upper angle of the abdominal section. The bleeding in this case was checked by the Matratzen stitches, which were first so successfully applied by Hocheneegg. The prognosis of subcutaneous rupture of the liver is never very favourable according to literary statistics, but probably depends largely on the extent of the rupture and the time that elapses after the accident before operating.

#### INVAGINATION CAUSED BY ADENOMA.

Haim showed a case on which he had operated for invagination of the bowel, said to be due to the presence of an adenoma. The patient was a male, æt. 65, who had suffered for some time from colicky pains in the abdomen, but no vomiting or meteorism was present at any time. After one of these attacks he was brought to hospital with stoppage of the bowel, with meteorism and vomiting on this occasion. There was tenderness on pressure over the ileo-cæcal region, no convulsive contractions of the bowel to be observed, nor uncontrollable vomiting, and neither stool nor gas passing from the bowel, although the patient confessed that he was fairly well otherwise. After considering all the symptoms, the case was diagnosed as strangulation of the ileus, with probably a tumour in the ileo-cæcal region as the cause.

On operating it was found that a portion of the small intestine had become invaginated immediately above the tumour, which was resected along with 15 centimetres of the bowel. The wound was closed in the usual manner, and the patient speedily recovered. The microscopic examination of the tumour proved it to be a malignant adenoma, which, according to clinical history, is a rare morbid process of the bowel.

#### NEPHRITIC CALCULI.

Konigstein gave the history of a case of a female from whom he removed a large stone from the pelvis of the kidney, which had its origin from an attack of gonorrhœa. The stone was of a dark red colour, about the size of a hazel nut, and embedded in a quantity of pus, mucus, and chalky matter.

She had been seven months married, æt. 22, and had had urethritis, cystitis, endometritis, and swelling of the left adnexa, due to gonorrhœal infection from the husband. On examination over the left kidney, which was tender, fluctuating and swollen to the size of two good fists, the diagnosis was conclusive that operation was desirable. She was generally ill with high fever and nephritic colic, and a large quantity of pus in the urine prompted immediate interference. The pelvis of the kidney was greatly distended, the stone and debris evacuated, after which the temperature fell to normal, and the patient speedily recovered.

#### COLOUR IMPRESSIONS ON THE SENSES.

Urbantschitch again treated the audience to a discourse on the various impressions produced by different colours. This condition is variable in different individuals. It sometimes happens that this mental condition is produced by one eye affecting the hearing on the same side of the body. The acuity of hearing has much to do with the production of colour. He finds that many persons have their taste perverted by colour, so much so that sugar may taste bitter or salt, and bitter sweet. No particular colour can be said to raise or lower this sensation as a general rule, but many individuals are subject to their influence. Any one with a favourite colour may have the sense excited by simply applying the rays to the skin. All these

experiments must be conducted when the body is at perfect rest, or fallacies will obtrude themselves.

## Hungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, December 7th, 1904.

### THE VALUE OF KOPLIK'S SPOTS IN EARLY DIAGNOSIS OF MEASLES.

IN the last number of the *Orvosi Hetilaps*, Dr. Navratil says that he had looked for the spots on the buccal mucous membrane, first described by Koplik as preceding by some days the general eruption of measles, and had found them in 24 cases. In one case they preceded the eruption by 6 hours, in 11 cases by 24 hours, in 3 by 32 hours, in 4 by 48 hours, in 2 by 3 days, and in 2 by 6 days. The spots were generally situated on the mucous membrane of the cheeks opposite the molar teeth, but occasionally also on the lips, beginning as slightly raised, bluish-white, circular, sharply-defined points, in size less than a pin's head, and surrounded by a narrow red areola. In a few days they generally increase slightly and become more prominent, and the areola enlarges and becomes irregular in outline. Their number varied between six and twenty, and the time during which they persisted from two to six days. They were most marked just before or at the time of the general eruption. They were not present in fourteen cases. Since they are never seen in other conditions accompanied by fever, they become of the greatest importance for the early diagnosis of measles. Navratil claims that the buccal eruption in measles was first mentioned by Gerhardt, and that their importance was recognised by Filaton in 1895, a year before their independent discovery by Koplik.

#### RADICAL TREATMENT OF VARICOSE ULCERS.

Dr. Polyák writes that, though some varicose ulcers on the leg heal with almost any dressing such as iodoform, zinc ointment, aïrol or xeroform, the greater number resist such treatment, or if they heal quickly relapse. For such, skin-grafting, after thorough disinfection of the ulcer, is by far the best local treatment, but whenever extensive varicosities are present, this is also unsatisfactory. The only radical treatment in such cases is to ligature the saphenous vein according to Trendelenberg's method before proceeding to the transplantation of the skin.

#### Dr. Huber has contributed a valuable paper on the PREVENTION OF RECURRENCES IN SYPHILITIC DISEASES OF THE EYE.

He believes that he prevents recurrence in syphilitic ocular disease by the following treatment:—In syphilitic disease of the choroid, mercurial inunctions should be undertaken for two years, the place of inunction being varied daily. The dose should not exceed 30 gr., and according to the age and constitution of the patient, doses of 8 gr., or 15 gr. are better. After every ten inunctions a pause of four days may be made. The best base for the mercurial ointment is lanolin. Longer pauses than three weeks should not occur in the whole two years. A pause of three months completely nullifies the treatment.

Potassium iodide has no curative influence on ocular syphilis, but is directly injurious on account of the conjunctivitis to which it predisposes, and should not be given in the majority of cases. Potassium iodide has only one use in the treatment of ocular syphilis, namely, to counteract the injurious influences of large doses of mercury.

## The Operating Theatres.

### GUY'S HOSPITAL.

NOVEL AND VERY EFFECTIVE MODE OF TREATMENT OF GENERAL SUPPURATIVE PERITONITIS.—Mr. ARBUTHNOT LANE operated on a man, the subject of an acute suppurative peritonitis, clearly the result of appen-

dititis, of three days' duration. The muscles of the abdomen were very rigid, and the abdominal wall did not move during respiration. An incision was made along almost the entire length of the outer margin of the right rectus. The distal portion of the appendix, which was abruptly kinked about its centre, was gangrenous, and the foul-smelling pus which had formed about it was retained by fairly firm adhesions. The abdomen contained a large quantity of turbid fluid, which was not exactly offensive in smell, but was certainly not sweet. The peritoneum covering the intestines was inflamed throughout. The appendix was removed and its stump inverted by a purse-string suture. The wall of the abscess was thoroughly cleaned with pads wet with normal saline solution. The intestines were then turned out through the incision and every portion of the abdominal cavity and of the protruding viscera were thoroughly irrigated with a very large quantity of warm normal saline solution. Owing to the retraction of the muscle wall it was obvious that the apposition of the margins of the incision would entail a great loss of time, a very serious matter in the patient's critical condition, and when effected would exert a very great pressure upon the dilated and inflamed intestines, and prevent the passage of their contents. In such cases, Mr. Lane said, he used to cover in the intestines with cyanide gauze soaked in saline solution, and retain them with a towel used as a binder; but recently he had adopted a more efficient method. He had brought the margins of the skin together with a continuous horse-hair suture, leaving a gauze plug or drainage-tube, or both, in the situation of the appendical abscess. The distension has then been relieved with turpentine enemata, supplemented by calomel or other drugs if necessary. When the peritonitis subsides he reopens the wound and brings the cut edges of muscle together. As the muscle wall is lax, and the intestines are no longer distended, this is done easily. By this means, he pointed out, the operation is performed rapidly and with the greatest possible efficiency, while the obstruction resulting from the distension of the intestines compressed by the rigid abdominal wall is removed. The intestines occupy the considerable interval between the edges of the muscles and beneath the thin, loose skin. By this simple means he had been able to save many lives, which would not have been the case with the methods usually employed.

**EXCISION OF THE RECTUM AND LOWER PORTION OF THE SIGMOID FOR CANCER.**—The same surgeon operated on a woman, *æt.* 36, who had a carcinomatous ulcer in the lower third of the rectum, about three-quarters of an inch in depth. It did not involve the vaginal wall, but it appeared to be adherent to the anterior surface of the sacrum. Mr. Lane remarked that he had for a long time advocated a more effective method of dealing with cancer of the rectum than that usually adopted, namely, of attempting the removal of the growth and the affected glands from below, such removal being rendered possible in extensive cases by the cutting away of a variable portion of the sacrum. This operation he considered barbarous and useless. It leaves the patient in discomfort, and often in misery, for the reason that it is often necessary to pass bougies in order to keep the aperture open, and the process of dilatation is painful in the extreme; the patient looks forward with dread to its performance. Again, he

insisted that it is impossible in a very large proportion of cases to deal effectually with the glandular infection by this method of operating. He considered all such operations a reproach to the surgery of the present day. The method he employs, he said, is equally applicable to the male or female, and is accompanied with very little risk. The patient was placed in the semi-prone, or lithotomy, position; the anus was closed by a suture; the parts were cleansed, and the lower part of the aperture of the bowel was encircled by an incision through which it was freed as far as the peritoneal reflection. The patient was then put on the back, and a long incision was made in the left iliac region. The sigmoid was exposed and the adhesions which usually shorten up its mesentery and possibly attach the intestine itself were carefully divided. These result from the obstruction offered by the growth. Mr. Lane said he had already fully described them. The freeing of these adhesions, he pointed out, enables the surgeon to bring the sigmoid out through the edges of the wound. The primary growth was then examined and the extent of glandular infection accurately determined. This, Mr. Lane demonstrated, can be done with perfect accuracy and great facility, and he had often been surprised with the extent of the glandular infection. In this particular case, although the primary growth was small and low down, glands of considerable size were present in the meso-sigmoid, eight inches from the primary growth. The sigmoid was ligatured well above any large glands. It was cut through above the ligature and the lower ligatured end was inverted into the distal bowel by means of a purse-string suture, and a tube connected with a removable rubber bag was tied into the upper part of the sigmoid. The lower part of the sigmoid, with an area of meso-sigmoid extending well beyond any glandular infection, with the rectum and meso-rectum, were all freed from their attachments the greatest care being taken to remove any secondary focus of infection. The abdominal wound was closed except where the proximal portion of sigmoid escaped through it. The patient was then placed in the semi-prone or lithotomy position, and the bowel was removed from below. Most of the anal aperture was closed, a plug of gauze being left in for a few days to drain the pelvis. When removed, Mr. Lane said, the remaining aperture either closes spontaneously or with the help of a suture.

The advantages of this method are, in Mr. Lane's opinion, (1) the complete removal of any fear of infection; (2) its freedom from any discomfort whatever after the operation; (3) the fact that the greatest possible benefit is obtained at a risk which is probably less than that incurred in the usually utterly inefficient method.

#### City Hospital for Diseases of the Skin, Dublin.

THE annual meeting of this hospital was held on November 30th, the Lord Mayor of Dublin in the chair. The report, which was read by Dr. C. M. O'Brien, stated that during the year ending December 31st, 1904, the attendance of patients numbered 658. Fifty-nine patients had undergone the light treatment. Of forty-nine cases of lupus, twenty-nine had been cured by this treatment. Of ten cases of cancer treated by rays, three had been quite cured. Among those who proposed resolutions at the meeting were Rev. J. Burke, Rev. P. Hayden, and Dr. Tobin.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 14, 1904.

**THE LONDON HOSPITAL "FUNDS" AND THE SMALL HOSPITALS.**

WE are glad to find that at length the Hospital Sunday and the King Edward VII. Hospital Funds have found a voice. As the trustees of large sums of money confided to their care by the public they are clearly open to criticism and should be prepared at all times to justify their action in particular instances. For our own part, we have always credited those bodies with the highest possible standards of aim and purpose, but, at the same time, we have never hesitated to point out what appeared to us to be defects in policy or in administration. Our views have been expressed with moderation, and we beg to refer all who are interested in this discussion to the tone of our remarks in a leading article of November 30th. It would be impossible for anyone having read that article to imagine that our position was prompted by any desire other than to secure by means of friendly criticism and suggestion a possibly more perfect justice in the administration of the grants issued by the Funds, and that our opinion of the inherent soundness and absolute good faith of those important public bodies was of the highest. Our aim, we repeat, is to secure an administration of the Funds that shall be free from the slightest suspicion of unfairness. The *Hospital*, an excellent journal, if not exactly a purely medical contemporary, has assailed us in the severest terms for a chance expression in a recent issue. The passage in question spoke of the host of small but deserving medical charities that had been injured in reputation and in income by not receiving grants from the Sunday and the King Edward Hospital Funds. The word "host" is obviously an over-statement that has escaped the editorial vigilance. The use of the word "host" would hardly be warrantable if applied to the

whole of the London hospitals taken together. Indeed, so clearly has the word been used in error that we wonder that any experienced editor could possibly take exception to a slip which he is bound to fall into sooner or later in his own columns, possibly and probably in a far more serious form. Indeed, forbearance towards obvious editorial lapses is a sort of unwritten but cardinal law of the better kind of journalism. However, we have no intention of declining responsibility for the statement in question. The Editor of the *Hospital* calls upon us in the name of responsible journalism to justify a certain phrase. In the name of responsible journalism and in support of the honourable traditions that have always governed THE MEDICAL PRESS AND CIRCULAR we withdraw that phrase and regret that it should have inadvertently crept into our columns. Sir Henry Burdett, however, must pardon us if we point out that, having disposed of this minor preliminary, we shall expect him to answer the rest of our criticisms. If he can furnish a full and satisfactory answer we shall be pleased to reconsider our criticisms and to give that fact the widest possible publicity. He must not think, however, that by pointing out a mere inadvertence he is relieved from answering the rest of the issues we have raised. That method of avoiding full discussion is not uncommon with controversialists of a certain type who imagine that to detect a flaw in an opponent's statements is to answer his whole question. Sir Henry Burdett has now come forward on behalf of the King Edward Hospital Fund. He may be reminded that similar criticisms to those under consideration have appeared in this journal for years past but have hitherto remained unanswered. Why, then, should he complain bitterly because of a delay of a week or two in answering his triumphant exposure of a clerical error? On the one hand, the principles of distribution adopted by a great public trust have been criticised year after year by an old-standing medical journal, but the editorial energy of Sir Henry Burdett lay dormant until a word was used which chanced to express in hyperbole more than was warranted by facts. If the public and the medical world can wait five or six years for an explanation of such serious matters from Sir Henry Burdett, surely he can wait a week or two for the explanation of a verbal slip in a journalistic article. It is to be hoped that now the subject has been fairly launched before the public it will not be allowed to drop before the constitution and the policy of the Hospital Funds are clearly stated and discussed. This result we anticipate with some amount of confidence, as it was only after our direct appeal to His Majesty the King that the matters to which we drew attention have been brought into the arena of public discussion. We doubt not that the well-known fairness of mind and love of absolute justice of His Majesty will ultimately secure full recognition of all medical charities, great and small, by his own Fund. Other matters raised in regard to the Funds will be dealt with in successive issues.

## CENTRAL BRITISH RED CROSS COUNCIL.

AN appeal is being made by Lord Knutsford, as chairman of the Central British Red Cross Council, for personal and financial support to be given to the excellent cause of which he is the official head. This cause, it will be recollected, is the preparation and organisation, in time of peace, of voluntary agencies for supplying help and reinforcement to the medical services of the Army and Navy in time of war. It may be argued that the energies of those interested in the welfare of the sick and wounded in war might be more usefully employed in securing an efficient medical department to the two arms of our national defence than in merely trying to supplement what is defective in their preparations. And so indeed it would be, if every campaign that has taken place had not shown the same waste of life and intensification of suffering, due to the same causes, reproduced with unerring regularity. We need hardly point out what those causes are—official neglect, official short-sightedness, and official incompetency. The price is always the same—in flesh and blood—and the price is always paid. Reform schemes are drawn up and improvements are set on foot with a flourish of trumpets; only to dwindle away and die of inanition as soon as the popular fervour is directed to some other object. It is of the essence of any scheme for properly serving the Army and Navy with doctors, nurses, hospitals, and stores that it should be possessed of an almost inexhaustible amount of elasticity, so that as wastage occurs and more troops are needed the department should be in a position to supply the medical reinforcements automatically. A fixed department with cut and dried resources soon reaches the limits of its capabilities, and then come haste, bustle, and blundering, with their accompaniments of extravagance and inefficiency. The lesson has been taught over and over again, and as many times neglected, so that the only man who could oppose the necessity for such work as the Central British Red Cross Council are engaged upon would be one who is thoroughly satisfied with the preparedness and aptitude of the medical arms of the Services. Such a man, if he exist, must be an incurable optimist, and may well be excluded from the scope of Lord Knutsford's appeal. But to those who admire our soldiers and sailors and are concerned for their welfare—to those, that is, who constitute the bulk of the nation—the work of the Red Cross Council must be a matter of deep concern, and one worthy of substantial assistance. The Council was formed in 1899 with the object of co-ordinating and bringing into line the admirable Associations which have sprung up sporadically to meet one or another deficiency in the humanitarian armament of the country, but which, if left to themselves, must unconsciously overlap and duplicate each other's work. Fortunately these associations have succeeded in obtaining recognition from the heads of the Army and Navy through the medium of the Central British Red Cross Council, and they may now be regarded as integral portions of the country's

defence. Everyone, therefore, should feel called upon to contribute to the maintenance of their resources in finance and *personnel*. But though the Red Cross Council is the channel of communication between the War Office and Admiralty on the one hand and the voluntary associations of the other, its position remains that of a mere channel, and it has in itself no other duty than that of helping unofficial bodies to do their work to the best advantage. For this reason there is no little danger that it may fail to excite the interest and support that it deserves, and we hope that Lord Knutsford's appeal may have the effect of drawing subscriptions to its funds and of bringing forward the leading people of counties and large towns to aid in forming committees to promote its objects. The haste with which the various voluntary hospitals were organised during the South African War and the regrettable waste of money that that haste entailed in many cases are still fresh in the public mind, nor should the want of harmony and direction that prevailed as the result of these spasmodic and irresponsible efforts be forgotten. No great naval war in which this country has been an active participator has occurred within living memory, but can it be reasonably doubted that similar confusion and ill-directed energy would characterise efforts to aid in mitigating the horrors of a long-drawn out sea-fight with a first-class power? The appeal comes at an appropriate moment when people are just recovering from the shock of the Dogger Bank incident and the startling suddenness with which it brought home to everyone that there is sometimes but one step between us and a European conflagration. A war with such a country as Russia would soon have exhausted the resources of even the reorganised Army Medical Service, and the voluntary agencies would have come forward to supply the want with their old vigour and, we fear, with their old want of co-ordination. *Si vis pacem para bellum* is as true of the humanitarian as it is of the bellicose preparations for war, and the way to aid the sick and wounded when the hour comes to succour them is by carefully organising in peace time the efforts of those who would help to that end. The Red Cross Council aims at establishing committees in each county, which will be left free to decide in what way they will render assistance—whether by preparing auxiliary hospitals, hospital ships, convalescent homes, or hospital trains. By this plan full play will be given to local aptitude and predilection. We hope that the response to the appeal will be commensurate with the natural importance of the issues involved.

## SOME ASPECTS OF OVERCROWDING.

THE general report of the Census Commissioners provides many interesting problems for the sanitarian, but we have still to deal with the moot question of overcrowding. The Census confirms the growing inclination of the population to leave the country districts and to flock to town. We find that persons occupied in agricultural pursuits

declined in numbers by 6·2 per cent. since 1891. Even this does not convey the most serious aspect of the phenomenon, for we find the decrease in the number of agricultural labourers actually 18·9 per cent. On the other hand there was an increase of 20·4 per cent. of persons employed as gardeners and in market gardening. This would show that it is high time we should recognise the new conditions under which agriculture must be pursued in Great Britain. The serious falling off in agricultural labourers mitigated by the increase of other classes employed on the land would seem to point unmistakably to the necessity for intense cultivation. This practically amounts to the need for a revolution in our system of land tenure. We require smaller holdings and a multiplication of allotments. It is clear that there is a movement towards decentralisation, but this does not really mean that the people are going back to the land; the real fact is, that large towns are spreading outwards, the suburban population is increasing by leaps and bounds, and we have here one explanation of the rise in cost of local government. It appears that the general increase in town population was 40 per cent. between 1891 and 1901, as against 12·2 per cent. between 1881 and 1891. The average increase for all London between the two last Censuses was 7·3 per cent. There was, however, a decrease in the dwellers of Central London, and also in Westminster and Chelsea. On the other hand we are confronted with the astounding increase of 193·5 per cent. in East Ham, 105·3 in Walthamstow, 87·4 in Willesden, 61·4 in Hornsey, 56·7 in Leyton, 43·7 in Tottenham, 13·5 in West Ham, and 30·4 in Croydon. This state of affairs is not confined to the Metropolis: the same conditions are found to exist in the large industrial centres of the provinces. Birmingham itself shows an increase of 9·2 per cent. only, but the accumulation of the population in the immediate neighbourhood has been far more rapid, and in Kingsfield and Northfield we find an increase of 101·5, at Handsworth 61·6, and at Smethwick 51·1. At Liverpool the increase was 8·8 per cent., but at Wallasey, on the opposite side of the Mersey, the increase was 61·2, and there is an equally marked increase in other suburbs of the great seaport. In spite of this agglomeration of the population, there is a distinct decrease in actual overcrowding, that is to say if we take overcrowding to mean that more than two people inhabit one room. This decrease is to be observed in all parts of the country, both urban and rural. We will deal with this in greater detail. At the last Census there were 6,260,852 houses inhabited, which shows an increase of 14·87 per cent. since 1891. The houses "in a state of building" showed an increase of 60 per cent., which is heavier than any previous record. The average number of persons per house in towns was 5·4 and in rural districts 4·6. The lowest urban average was 4·34 at Great Yarmouth, and the highest was 8·85 at Devonport. The average for London was 7·93, which compares with 7·73 in 1891. But the density varied considerably

in different districts. For instance, in Stepney 33 per cent. of the entire population was living in an overcrowded state; even this was not the worst, for in one of the parishes, St. George's-in-the-East, the overcrowded percentage was 45. The total number of persons living in an overcrowded condition was 481,653 in 1891, dropping to 392,414 in 1901, showing respectively an average of 11·2 and 8·2 per cent. of the total population. This is a result which, though satisfactory, should spur on local authorities to do still better in the future. We have heard a great deal about the alien invasion, though this is bad in the results it impels on certain restricted districts, the general outcry has been somewhat exaggerated. It is true that foreign population in our midst has trebled since 1861. At the last Census there were 106,000 more than in 1891. More than half of the total were to be found in London, and 20,000 in the adjoining counties. The remainder of the foreigners were almost entirely to be found in the large seaport industrial centres. While in London generally there were 30 foreigners for every 1,000 inhabitants, in Stepney there were 182 foreigners for every 1,000 inhabitants, which compared with 113 in 1891, and 57 in 1881. In Holborn, the proportion was 92 foreigners to 1,000 of the population. There is, therefore, some justification for the statement that the presence of the poorer foreigners connotes overcrowding, and although the evil may not be very general or very great, yet we know what deteriorating effects on the whole population danger-spots have. It is clear that much still remains to be done not only in inducing the people to go back to the land, but also in improving the poorer quarters of our great cities. That we have reduced considerably the number of single room tenements, and, in fact, all tenements with rooms below the number of five, should be an incentive to greater efforts in the future.

### Notes on Current Topics.

#### The Metropolitan Hospital Sunday Fund and the Small Hospitals.

WE have received a letter from the Honorary Solicitor of the Metropolitan Hospital Sunday Fund calling in question several statements that have appeared in THE MEDICAL PRESS AND CIRCULAR. This action of the Fund we welcome as a preliminary step to full discussion of the administrative policy of an important public body. We hope to enter fully into the points raised in an early issue. Similar criticisms have been published for years past, but as the Hospital Sunday Fund has hitherto allowed them to be taken by default as granted in the absence of any question or contrary assertion, there can be no overpowering need for hurry in our reply. We note a tendency, moreover, on the part of our correspondents to confuse issues. Meanwhile, we can assure the Hospital Sunday Fund of our complete sympathy and respect, which is in no way alienated by what we conceive, perhaps mistakenly, to be

our duty in inviting public attention to certain points in the policy of the Fund that appear more or less open to improvement. If the Fund can justify their system of grants and of withholding grants we shall be the first to withdraw our criticisms and to accord our hearty approval.

#### Suburban Sanitation.

IN no surroundings is there need for more careful sanitary supervision than in the suburbs of our large towns. They usually appear as typical abodes of health, with their roomy houses, green lawns, and clear skies. But just on account of this appearance of rude health, so to speak, is there the greater risk of overlooking the want of proper sanitation and hygienic precautions. It is not uncommon to find, especially in rapidly-growing districts, that a water supply or a drainage system is being strained beyond what it can bear. The sewer that was large enough for a population of five thousand is inadequate for one of seven. It is unusual to find in suburban districts any rigorous attention given to the supervision of the food supply. Milk which could not run the gauntlet of the sanitary inspectors in a town may often be purveyed without question outside the town limits. There is, again, but little care taken as to the site of new buildings. Many are put up with haste on ill-drained fields, or even on rubbish-heaps, used for filling quarries or sandpits. Scattered here and there between the houses of the well-to-do are little congested areas of dwellings for the poor. In them the conditions are often worse than in the crowded tenements of the city, for supervision by the health authorities is more often absent. There may be no water supply, and for sanitary convenience only a privy which is rarely cleaned. A well or pump in close proximity supplies the drinking water, and near at hand is an ash-heap containing garbage of all sorts. This statement of conditions is true of many a suburban district, though, of course, on the other hand, many are veritable health-resorts.

#### Human and Bovine Tuberculosis.

THE last word in the controversy as to whether human and bovine tuberculosis are the work of the same or different organisms remains yet to be pronounced. Professor Koch still sticks to his guns, but none of his arguments or their own experiments have yet convinced the Royal Commission on Tuberculosis that there is any recognisable difference between the organisms. Indeed, their conviction as to the identity of the bacilli is fairly well established. It is interesting, therefore, to note that the recent report of the Imperial Commission on Consumption appointed by the German Government some time ago asserts strongly that the bacilli are absolutely distinct from one another biologically, and that one bacillus can never be made to develop or change into the other. On the other hand, though they find tuberculosis in man to be generally due to the bacillus of human tuberculosis, it may in some cases be caused by the bovine bacillus. In fifty-six cases of persons

dead of tuberculosis, they found the human bacillus in fifty and the bovine in six. Three of the latter were young children, whom it is reasonable to assume may have contracted the disease from infected milk, and the practical lesson that stringent precautions should be taken to eliminate tuberculous cows from dairy herds receives additional confirmation by this finding. After Koch's startling pronouncement at the International Tuberculosis Congress in London, there was considerable danger that those who defied the regulations would quote his authority to support their attitude; fortunately, now they will not have that excuse.

#### Pneumonia in Chicago.

WE drew attention not long ago to the extraordinary death-rates due to pneumonia in some of the American cities, and to the attempt which is being made by a committee of experts to discover some method of meeting this veritable scourge. In Chicago the deaths from pneumonia make up no less than 16 per cent. of the total, and have shown during the past few years an alarming tendency to increase in number. In fact, in 1900, the percentage was 13½, and each year since shows a regular increase. It is but little satisfaction that at the same time as this change has been going on there has been a slight diminution in the number of deaths from phthisis, for it is not nearly enough to make up for the increase of the other disease. It is, indeed, a discouraging thing to sanitary practice that at the moment when we seem to be gaining some control over most of the infectious diseases, pneumonia denies all restraint. Last year in Chicago it caused 50 per cent. more deaths than all the other infectious diseases combined, including cerebro-spinal meningitis, erysipelas, diphtheria, influenza, malaria, measles, mumps, scarlatina, small-pox, typhoid fever, whooping-cough, and puerperal fever.

#### The Action of Sugar on the Uterus.

SOME of the simplest remedies lie ready to one's hand; so close, in fact, that they are persistently overlooked. Many have been the drugs used and various have been the devices employed by the harassed accoucheur to expedite labour, and yet had he known it a lump or two of sugar would have done all he wanted. At least, so one would gather from the researches of Keim, (a) who had been acquainted with the fact for six years, but hesitated to make it fully known till stimulated by Marquis, another worker in the same field. Lactose he believes to be the most efficacious sugar to administer, and this is readily absorbed in late pregnancy owing to the usual hepatic insufficiency. In labour, if the os is a long time in dilating, the glycogen in the blood is used up and the uterine muscle needs more carbohydrate to help it in its work. If this deficiency be supplied by the administration of sugar, the muscle gains fresh vigour and begins to contract with renewed

(a) *Archiv. gen. de Med.*, September 27th, 1904.

energy. The best time to give sugar is two and a half hours after dilatation has begun in multiparæ and three and a half hours in primiparæ. When, however, the os has dilated considerably, giving more sugar hurries on the process of labour markedly, especially if inertia is threatening. A case is quoted of a multipara, whose labours usually lasted one or two days, being given sugar fifteen hours after her pains began. Within one hour the child was born. Stress is laid by Keim on the fact that, unlike drugs such as ergot and quinine, sugar is not toxic, is always available, and acts not only on the muscles of the uterus but also on those of the abdominal wall. The prescription has the added advantage of being a palatable one. Doubtless the accoucheur of the future will improve on crude lactose as the vehicle of administration of carbohydrate, as it may happen that shortly a box of Fuller's sweets will be deemed as essential an item in the equipment of the midwifery bag as forceps, chloroform, and perchloride tabloids. We trust that the present rise in the price of sugar may not interfere with the proper trial of the remedy.

#### The Surgical Examination at Edinburgh.

It is with considerable interest that the profession will await the further inspection of the final surgical examination of Edinburgh University as ordered by the General Medical Council. With this pending it would be unfair to make any comments on the questions at issue, as there are serious differences of opinion, if not of fact, between the visitor and inspector on the one hand, and the medical faculty of the University on the other. We are not precluded, however, from criticising the method and manner of the report of the visitor and inspector. These gentlemen, who, no doubt, have performed a difficult duty with perfect honesty and *bona fides*, seem to have given an unusually wide meaning to the terms of their commission. They took no steps to discover the lines laid down for their guidance in the Standing Orders of the Council, and, in consequence, they erred both by omission and commission. On the one hand, they have not kept, at any rate as official documents, diaries of their inspection, and have therefore been unable to point to specific instances of the general faults of which they speak. On the other, they include in their report a quantity of extraneous matter in the way of general discussion of the ideals of medical education and examination. Under the circumstances, the General Medical Council has had practically no alternative but to order a re-inspection of the surgical examination at Edinburgh. We may add that it is fortunate for Sir George Philipson and Mr. Bryant that they had not to submit their report for the criticism of the Regius Professor at Cambridge or any other medical stylist. Many of their sentences are so long and complicated as to recall vividly the famous letters a certain peer addressed to the *Times* a few years back on ecclesiastical subjects.

#### Red Cross Work in Japan.

MISS McCAUL, in her recently published book on her experiences in Japan and Manchuria, gives an account of the organisation of the Japanese medical department which should make the mouths of our reformers water. Miss McCaul was sent to Japan to inspect their Red Cross work in actual operation, and thanks to the courtesy she received she was able to make a pretty complete study of it. The chief reason of her success lay apparently in her assuring the authorities that she "had come to learn and not to teach," and as our little allies take a considerable pride in their work, and resent being patronised, this declaration acted as the "open sesame" of the hospital doors. What struck Miss McCaul particularly was that the Red Cross Society is a great national organisation permeating every class in the country; none are too noble and none too poor to be influenced by it. One plain "nurse" that Miss McCaul met afterwards proved to be the Marchioness Nabéshimá—a lady of high rank and distinction. But although nursing sick soldiers is regarded as a pleasure and a duty by ladies, Manchuria does not seem to suffer from Sir Frederick Treves' "plague of women." for all the women know how to do their work and make it their business to carry it out without regarding their toilettes and prospects of getting husbands. Great care is bestowed on the preparation and transport of food, whilst all along the route arrangements are made for the soldiers to fill their water-bottles with sterilised water. When one compares their enlightened, scientific, and orderly procedures in all these essential points with the scurry and muddle of the South African War, one is forced to admit that new civilisations have advantages which are denied to older ones. It would be rather humiliating to ask Generals Oyama or Kuroki to take charge of our War Office for five years; but we are inclined to think that worse suggestions might be, and have been, made in connection with Army reform.

#### The Public Health Laboratory at Boston.

No right-minded person thinks of questioning the dogma that "Boston is the hub of the universe." It is a necessary consequence that its new bacteriological laboratory "licks creation." Seriously, the organisation of public health work in Boston is as admirable a system as has yet been devised, and the description of the laboratory, as given in one of our American contemporaries,<sup>(a)</sup> is enough to rouse the envy of our sanitary officials at home. The laboratory supplies medical men with outfits to procure specimens of suspected sputum, membranes, blood, and so on, and these are distributed from, and collected at, various stations throughout the city. An ingenious device is made use of to obviate delay in the examination of diphtheria specimens which arrive after closing time. The laboratory closes at six,

(a) *Boston Med. and Surg. Journ.*, November 10th, 1904.

but, side by side with a big box for receiving other specimens is a chute for diphtheria specimens which leads directly into a small incubator. By this means an examination can be made, and a report given as soon as the laboratory opens in the morning.

#### The Study of Greek.

THE question of demanding Greek as a compulsory subject from students entering the ancient Universities has come up again in practical form. Oxford has already voted on the matter, and Greek is to remain obligatory on the banks of the Isis. Cambridge, however, has not yet registered its opinion; but a long and interesting debate has taken place on the report of the Studies and Examinations Syndicate containing the proposal. To medical men the question is interesting principally as affecting candidates for scientific and medical degrees, and there will be few, we think, who would be in favour of requiring a man who has shown a marked aptitude for the natural sciences to be forced to present a smattering of Greek as a preliminary to the serious study of his life. The difficulty of the Greek language is admittedly great, and the amount of ground that has to be broken in the way of grammar and accidence before any possible acquaintance can be made with the authors in the language demands years of close and attentive study. It is beyond dispute that the disciplinary value of such study can be obtained in many other ways, all of which would place the student in a position of more practical advantage than that of being able to hammer out a mediocre translation of Thucydides or Homer with the aid of a dictionary and a grammar. It is a compliment to Greek and Greek scholars to admit that proficiency in the language is reserved for the few, and we are glad to see that the Master of Trinity and the Provost of King's recognise the superior advantages of other studies for men whose minds are cast in a different mould from their own. It is much to be hoped that if the whole of the Syndicate's recommendations are not carried, the plan advocated by the President of Queen's may be adopted, and that while Greek remains compulsory for men seeking an Arts degree, an alternative degree, namely, a B.Sc., may be created for science students who would not have to pass in Greek as a compulsory preliminary to working for it.

#### Bacteria in the Stomach.

No clinical investigation of a case of gastric disease is now complete unless a chemical examination of the contents of the stomach be made. The value of this is rightly insisted upon by those who endeavour to place the affections of this organ upon a scientific basis. Microscopical examination of the material thus provided is of equal importance, for the recognition of undoubted cancer cells may be the only way of confirming a hitherto doubtful diagnosis of malignant disease. Now it seems as if a bacteriological investigation is also necessary if the physician is to have a right comprehension of the

case under his charge. The appearance of sarcinae and torulæ has been held to be valuable evidence of the existence of fermentative conditions within the stomach, whether in certain varieties of dyspepsia or in simple dilatation of the organ. Dr. E. Palier, of New York, working in Berlin, has examined thirteen samples of gastric juice from different classes of stomach disease. The results of the bacteriological tests which he has conducted with a view to further elucidating the pathology of dyspepsia and carcinoma are most instructive. Thus, in all cases of malignant disease staphylococci were found in great abundance. The so-called lactic acid bacillus, the same organism as is concerned in the souring of milk, is found to possess a flagellated extremity, and, because it is not a straight rod but bent in the middle, the author would apply to it the name of *Vibrio geniculatus ventriculi*. This germ will develop well in any medium which is deficient in hydrochloric acid, so that it is found plentifully in carcinoma. In cases of hyperchlorhydria, on the contrary, this organism is absent, but different varieties of yeast fungi and sarcinae flourish instead. These latter are, of course, absent in cancer. A knowledge, therefore, of the flora of the stomach will probably be of some assistance to the physician as well as to the surgeon.

#### Alcohol and Tremor.

A FINE muscular tremor of a static character is generally considered to be one of the signs of chronic alcoholism. When nervous control is impaired to such a degree that the condition becomes practically chronic, the tremor can be relieved up to a certain point by greater indulgence in the drug. The popular idea that alcohol "steadies the nerves," which is still only too prevalent, has probably arisen from a knowledge of its action in this respect. The tremor produced in this manner is toxic in nature, acting through the nervous system, though when once well established it is difficult to distinguish from other varieties of nervous tremor. It would appear that alcohol may occasionally be of some therapeutic value in controlling tremors of a totally different origin. The case recorded by M. Mayet (a) is worthy of note in this respect. The patient was a man, æt. 52, who presented the symptoms of disseminated sclerosis, from which he had suffered for many years. The volitional tremors were very severe, so that eating and drinking were difficult. The man had found, however, that these movements were almost entirely controlled by drinking a large quantity of wine; at any rate, he was by its means enabled to earn his living as a labourer. He had other signs of alcoholism, such as impaired digestion, disturbed dreams, and occasional excitement. An attempt was made as soon as he came under medical observation to substitute some other drug for alcohol in order to lessen the amplitude and intensity of the intentional tremors associated with his nervous disease, but each one was a failure.

(a) *Lyon Médicale*, November 27th, 1904.

Alcohol was the only thing that appeared to control them to anything like a reasonable extent. The *raison d'être* of its action in this case is not obvious, and it can hardly be supposed that the beneficial results will be permanent.

#### Alterations in Examination of the Royal University, Ireland.

THE Senate of the Royal University of Ireland has decided upon an important alteration in the examination for medical degrees held by the University. Up to the present the system of examination has been that first a general examination for all candidates is held, and that all candidates who obtain over a certain percentage of marks are allowed to present themselves for a further honours examination. The actual awards of honours and exhibitions are then made on the results of this honorary examination. This system has met with adverse criticism from both examiners and students for a considerable time, and various efforts have been made to have it altered. In future two separate examinations will be held simultaneously, one for pass candidates only, the other for honours candidates only. When entering for the examination, each candidate must state at which of these examinations he elects to present himself. A candidate who has entered for the honours examination may be allowed to change to the pass examination on giving a satisfactory reason for doing so, at least one week before the date of examination, but under no circumstance will a candidate who has entered for the pass examination be allowed to change to the honours examination. Honours and exhibitions will be awarded on the results of the honours examinations alone. It is impossible to offer a definite opinion on the merits of this system until it has been tested, but we are of opinion that it is preferable to the previous examination. We are, however, further of opinion a rule ought to have been added to the effect that candidates who had failed on a previous occasion to satisfy their examiners at either the pass or the honours examination should not be allowed to subsequently present themselves for the honours examination. Honours and exhibitions should be reserved for the most deserving candidates, and the most deserving candidate is not the man who has been rejected at a previous examination.

#### PERSONAL.

It is stated that his Majesty the King on his visit to Manchester next spring will take part in the inaugural ceremonies of the Sanatorium for Consumption in Delamere Forest, an institution which owes its existence to the generosity of the late Mr. W. J. Crossley.

MR. GEORGE C. FRANKLIN, Surgeon to the Leicester Royal Infirmary, will deliver his Presidential Address to the British Medical Association meeting at Leicester on Friday, July 25th, 1905.

THE address in Medicine at the Leicester Meeting will be delivered by Dr. Henry Maudsley, and the address in Surgery by Mr. C. J. Bond, of Leicester.

THE Earl of Derby, K.G., presided at the first dinner of the Manchester Medical School after its amalgamation with the newly founded University of Manchester.

PROFESSOR ARTHUR ROBINSON, of King's College, London, has been appointed to the Chair of Anatomy at the University of Birmingham, in succession to Professor B. C. A. Windle, now President of Queen's College, Cork.

THE Wilhelm Order, which is awarded in recognition of services rendered in the cause of the public welfare, has been conferred on Professor Robert Koch.

It is reported that Dr. William H. Welch, Professor of Pathology at Johns Hopkins University, Baltimore, will succeed Professor Osler in the Chair of Medicine.

DR. J. M. ENGLISH, New Westminster, British Columbia, has been appointed Resident Physician at Quesnel, in place of Dr. A. D. Morgan, who has resigned.

DR. HINDLE, who has ceased practice, and is leaving Askern, in Yorkshire, was on Thursday last, with his wife, the recipient of several handsome presentation gifts from friends and patients.

MR. JOHN TWEEDY, the President of the Royal College of Surgeons, on the 6th instant unveiled a window which has been erected in memory of Mr. William Cadge, Fellow of the Royal College of Surgeons, in Norwich Cathedral.

THE United Hospitals Clinical School of Liverpool held its first annual dinner at the Adelphi Hotel on December 3rd, Dr. William Carter, J.P., Senior Physician to the Royal Southern Hospital, being in the chair.

At a recent meeting of the Liverpool Medical Institution, Mr. E. R. Bickersteth, F.R.C.S., formerly president of the institute, and this year president of the Royal Infirmary, was cordially congratulated on the completion of his fiftieth year of membership of the institution.

MR. PRIESTLEY SMITH has resigned the appointment of Honorary Ophthalmic Surgeon to the Queen's Hospital, Birmingham, to the great regret of everybody connected with the institution.

PROFESSOR DEBOVE has been unanimously re-elected Dean of the Medical Faculty of the University of Paris.

PROFESSOR ARNOLD HELLER, Director of the Institute of Morbid Anatomy at Kiel, has been elected Rector Magnificus of that University.

As previously announced in this journal the Nobel Prize award for Chemistry has this year been made to Sir William Ramsay, Professor of Chemistry at University College. The sum of money attached to each prize is about £7,825.

KING OSCAR of Sweden made the Nobel Award in Physics to Lord Rayleigh, Professor of Philosophy at the Royal Institute.

ON the same occasion at Stockholm the prize in Medicine and Physiology was bestowed upon M. Pavloff, Professor at the Military Academy of Medicine in St. Petersburg.

PROFESSOR WINDLE, M.D., F.R.S., of the University of Birmingham, who was recently appointed President of Queen's College, Cork, was honoured on Thursday last with a public dinner under the auspices of the University at the Grand Hotel, Birmingham. Sir

Oliver Lodge, Principal of the University, presided over an enthusiastic gathering of Dr. Windle's late colleagues and friends, anxious to show their appreciation of his work in the past.

DR. GRAMSHAW, of York, has been presented by the Sheriff Hutton Free Gift Society with a handsome testimonial bearing the inscription—"Presented to F. Sidney Gramshaw, M.D., F.R.C.S. Edin., as a token of respect and esteem for nearly thirty years of faithful service.

### Special Correspondence.

(FROM OUR SPECIAL CORRESPONDENT.)

#### SCOTLAND.

LEUKÆMIA AND ALLIED DISEASES.—On Thursday last Professor Muir, of the University of Glasgow, delivered an instructive address before the Glasgow Medico-Chirurgical Society on this subject. By means of the lantern he showed numerous slides of the various forms of cells and the changes they undergo in the medullary form of leucocythæmia or what has often been called spleno-medullary leukæmia, as well as in the lymphoid form of the disease. In the course of his address Professor Muir stated that while in the chronic forms of the disease the rule was to find the spleen much, and oftentimes enormously enlarged, in other cases where the disease ran its course rapidly there might be very slight enlargement of the spleen. Further the enlargement of that organ was due to the multiplication of the cells or corpuscles and not to any marked fibroid change in the enlarged spleen. Coming to the diseases allied to leukæmia he referred to Hodgkin's disease, and to the confusion which has long existed with regard to the numerous terms applied to the general enlargement of the lymphatic glands throughout the body, such as lymphadenoma, lymphæma, lympho-sarcoma, etc. In this form of disease the cell proliferation was not so pronounced as in leukæmia, and there was certainly a distinct tendency to connective tissue growth—to a fibroid condition—existing in a marked degree. It was his opinion that there was an infective process at work in Hodgkin's disease, and that it was not of a tuberculous character. He made reference to the Transactions of the Pathological Society of London in 1878, on this subject, and to the writings of several American authors with whose views he was disposed to agree. Drs. Workman, Lindsay Steven, and Hunter took part in the discussion which followed, and generally expressed themselves as in complete agreement with the conclusions arrived at by Professor Muir, that while no organism had yet been found as the cause of the disease, that it was at least not a tuberculous process. On the motion of the chairman, Dr. R. M. Buchanan, a hearty vote of thanks was accorded Professor Muir for his instructive address which was listened to by an unusually large number of members of the Society.

THE GLASGOW MEDICAL CLUB.—For some years there existed in the city on the south side of the River Clyde, what was called the Southern Medical Club, the membership of which was composed largely but not exclusively of medical men belonging to the southern district of the city. A short time ago it removed its habitation to much more commodious premises situated at 22, Carlton Place. The name of the club has been changed to "The Medical Club," with the intention of embracing within its membership as many members of the profession throughout the city and the suburban districts as can be prevailed upon to join. The subscription is £1 1s. per annum, without any entrance money. There is a large room, forming the library, which is admirably adapted for holding medical society meetings. It is there the Southern Medical Society holds its meetings every alternate Thursday evening. It is also equipped with a billiard room, as well as a card room, and ample accommodation for caretaker. Since removing to the new premises a considerable

accession to the membership has been made, the new members being drawn from the different districts of the city. It is hoped that many others may see their way to join, and when the existing lease expires, as it does in four years, still larger and more central premises in the centre of the city may be procured. There is no reason why Glasgow, with over six hundred medical men practising in the city and suburbs, should not have a large and flourishing club where, perhaps, the various medical societies could hold their meetings, and where country members might find comfortable accommodation if required when visiting the city, with the advantage of friendly intercourse with their fellow practitioners. The club is managed by general, house, library, and amusement committees. It is proposed to set apart one evening of the week as a "house" night, and to have occasional social evenings. One such, held recently, was a great success, the musical talent being quite up to the average if not beyond it of such gatherings. With a further increase in the membership of the club its sphere of usefulness would be largely extended, and the interests of the profession might, perhaps, be more strictly conserved than at present obtains. This would at least be one way, and a pleasant one, of arriving at the accomplishment of such a very desirable end.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

#### HOSPITAL FUNDS AND SMALL HOSPITALS. To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This question is well worth full discussion. It would be interesting if "A Small Hospital Physician" would clearly explain what he means when he writes that "under the conditions that rule the hospital medical world of London, the only chance for any man not born into the purple lies in obtaining an appointment at a small special hospital." Special departments exist at all general hospitals; and if the unnecessary special hospitals were closed these departments would be enlarged, and their staffs increased to meet the demand upon them. Does your correspondent mean to imply that appointments to the staff of general hospitals are made with regard to anything save the professional attainments and personal qualities of the candidates. The appointments are controlled by professional opinion, and governed by the merit displayed throughout a career under the eyes of future colleagues when the candidate is an old student of the hospital, or well-known by careful inquiry when an outsider. The personal character, the professional ideals, the scientific and practical work and attainments of applicants for special appointments at general hospitals are thoroughly understood by those having the gift of the posts; and the danger of the offices being filled at the worst by ignorant adventurers, or at the best by men having no valid claim to the title of specialist is in these institutions reduced to the lowest possible point. It is not less to the interest of the poor, the public, and the profession, as well as of progress in medical science that professors of specialism should present ample guarantees of their claims to recognition and distinction; and these guarantees are not provided under the conditions which exist at the great majority of special hospitals.

I am, Sir, yours truly,  
Cavendish Square,  
December 7th, 1904.  
HENRY SEWELL.

#### CELLULOID COMBS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—On page 610 of THE MEDICAL PRESS AND CIRCULAR you kindly sent me, you say, in connection with celluloid combs, "unrecognisable as celluloid save to the expert in such matters." May I call your

attention to a method of detection which occurred to me, and which is as simple as I believe it to be infallible: Heat a metal skewer in a candle flame, touch the comb with it, and smell the fumes. If the article is tortoiseshell, the smell is of burnt bone, familiar in the horse-shoeing forge. If it is celluloid, the smell is sweet and camphoraceous.

If you try this method you will at once perceive the difference. If it is done on the inside surface of the comb, no disfigurement results.

I am, sir, yours truly,

HAROLD NUTTALL, M.A., M.D.

Bryn-y-Craig, Conway Road, Colwyn Bay,  
December 7th, 1904.

### Obituary.

JOHN KENNEDY, M.D.R.U.I., M.Ch.

THE death is announced, in his 66th year, of Dr. John Kennedy, of Farnham Place, Old Trafford. Dr. Kennedy took his degree of Doctor of Medicine in the Queen's University of Ireland exactly forty years ago, and two years later he qualified as M.Ch. He was one of the oldest and most respected members of the medical profession in Manchester.

EDWARD BATEMAN HECTOR, M.D. EDIN.

WE regret to announce the death of Dr. Edward B. Hector, of Castle-Douglas, who died suddenly on the 2nd inst. He returned from a visit about four o'clock, and a few hours later was found in a state of collapse, and expired soon afterwards. The deceased, a native of Montrose, took his M.B.C.M. Edin. degree in 1883, and M.D. in 1902. Dr. Hector had an extensive local practice, and was medical officer for the parishes of Balmaghie and Parton. His wife, a daughter of Dr. Munro, Moffat, died last year.

WILLIAM G. VAUDREY LUSH, M.D. LOND.,  
F.R.C.P. LOND.

DR. W. G. VAUDREY LUSH, physician at the Dorset County Hospital, died at Weymouth, on December 7th. He had just addressed a meeting of the committee at the hospital when he fell from his chair and expired. Dr. Lush, who took an M.B. degree with a treble first class in 1865, and that of doctor of medicine at London University in the following year, was one of the best-known practitioners in Dorset. He was an active Churchman and county secretary of the Queen Victoria Clergy Fund, and leaves behind him a large circle of friends and acquaintances. He made numerous contributions to medical literature.

CHARLES WILLIAM CHALDECOTT, M.R.C.S. ENG.,  
L.S.A.

WITH much regret we announce the death of Mr. Charles William Chaldecott, of Dorking, Surrey, on November 5, at the age of seventy-six. He received his professional training at St. Thomas's Hospital, where he studied from 1848 to 1851, and distinguished himself much as a student. In 1851 he became qualified as M.R.C.S. Eng., and L.S.A., and took over his father's practice at Dorking. Until his retirement in 1901, no less a period than fifty years, Mr. Chaldecott was in the active pursuit of a large practice. He was twice married, his first wife, who died in 1866, being a sister of the late Sir John Simon, and he leaves a family of nine sons and daughters. In him the profession has lost one of the typical representatives of the old school of honourable medical men of high social standing.

DR. D. ASTLEY GRESSWELL.

BY telegram we have been informed of the death of Dr. D. Astley Gresswell on December 10th, at Melbourne. The deceased was Chief Health Officer for the Colony of Victoria, an appointment he has held some fifteen years, during which he has inaugurated far-reaching sanitary improvements in the city of Melbourne and throughout the colony. He was an indefatigable worker, and his patience and persevering industry were well known. He is the author of a work on "Scarlatina" and joint author with his brother, Mr. G. Gresswell, of a treatise on "Comparative Pathology." He took the degree of M.B. Oxon., in 1881, and M.D. of the same

university in 1889. He was also a member of the Royal College of Surgeons of England, J.P. for Victoria, and was much appreciated as a genial, cultured man.

### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. W. Massen, professor of midwifery and gynaecology in the University of Odessa. Dr. A. Sanchez Herrero, professor of clinical medicine in the University of Madrid. Dr. K. von Stellwag, formerly professor of ophthalmology in the University of Vienna. Dr. Albert Reeder v. Schellmann, formerly professor of dermatology in Vienna, at the age of seventy-eight years. Dr. Alfred Zimmermann, a Vienna staff surgeon, who was a very experienced operator, especially in abdominal cases. His death was due to septic poisoning. He was only thirty-nine years of age. Dr. Redtenbacher, one of the medical officers of the Vienna General Hospital. Dr. Hugo Mittenszweig, one of the editors of the Berlin *Zeitschrift für Medicinalbeamte*. Dr. Robert Langerhans, *privat-docent* of pathological anatomy in the University of Berlin. Dr. Joaquim Pereira da Cunha, professor of ophthalmology in the University of Rio de Janeiro.

### Literature.

#### TRANSACTIONS OF THE MEDICO-LEGAL SOCIETY. (a)

THE constantly growing importance of the relations between the two great professions of law and medicine has recently been marked by the foundation of the Medico-Legal Society. The first volume of the proceedings has just been published, and contains some papers of great interest. One burning question appears continually throughout its pages, namely, the subject of coroners' inquests. Mr. Troutbeck gives a very interesting paper on "Inquest Juries," in which he goes very fully into their advantages and defects; and there is no doubt that if there were no other advantage except that "the jury constitutes the only practical check on the coroner," it would be a mistake to try to abolish them.

Dr. Littlejohn gives a valuable paper on "Medico-Legal Post-mortem Examinations," which necessarily deals with the same subject. Undoubtedly the medical profession feels that there is too much uncertainty, and perhaps laxity, in the matter of having autopsies in cases of sudden death; but this is owing to the present state of the law, and it is one of the functions of such societies as this, to help to educate public opinion in the matter, as it is only in this way that reform can be expected. But Dr. Littlejohn emphasises one point that is too often forgotten by teachers and students alike—that no subject in the curriculum is more neglected than medical jurisprudence. This ought not to be the case, as no practitioner is able to be certain that he will not at some moment find himself involved in a case of the first importance.

Mr. Wellesley Orr gives a short paper on "Cremation," showing its steady if somewhat slow increase in popularity. One of the great arguments against cremation has, of course, been that destruction of the body may facilitate crime, but Mr. Orr enumerates the precautions taken by the Cremation Society to guard against this; but even so it will take time to educate the public up to realising this, and till then there is always a risk that a man might be emboldened to commit a crime if he knew that the body was to be cremated.

The price of the volume is rather excessive, and the Society would be wise if they could see their way to lowering it, so as to increase the circulation.

#### ASTHMA IN RELATION TO THE NOSE. (b)

The greater part of this little volume consists of an

(a) "Transactions of the Medico-Legal Society for the years 1902, 1903, 1904. London: Baillière, Tindall, and Cox, 7s. 6d. 1904.

(b) "Asthma in Relation to the Nose." By Alexander Francis M.B., B.C. Cantab. Pp. 136. Price 5s. net. London: Adlard and Son, 1903.

appendix containing brief notes of over 400 cases of asthma treated by the author's method, and we can at least say that they supply ample *prima facie* evidence of the value of the procedure which he has discovered. The opening chapters of the book deal with the etiology of the disease, Dr. Francis' view being that it is due to spasm of the bronchial muscles induced by reflex action. The question of the relation of nasal lesions to asthma is fully dealt with, the conclusion being that asthma is not directly due to any mechanical obstruction of the nasal passages, and only rarely to reflex nasal irritation. The novel conception led up to is, that in asthma a morbid connection subsists between some part of the nose and the respiratory centre, whereby that centre is thrown into a state of unstable equilibrium. This theory has been arrived at empirically, by the observation of the effect of cauterising the nasal septum, which is the plan of treatment advised. Contrary to the usual opinion, the author holds that the prognosis is in inverse ratio to the extent of the nasal lesion—polypus cases being the least, and those in which the nose appears healthy the most, hopeful. It is impossible to express an opinion on the value of the treatment until further trial has been made, but we feel strongly that Dr. Francis offers cogent reasons for the faith that is in him, and if his treatment yields even half as good results in the hands of others as it has done in his, he need not feel that his book has been written in vain.

#### THOMSON AND MILES' MANUAL OF SURGERY. (a)

THE second volume of this work, dealing with "Regional Surgery," maintains the excellent characters of the first volume which we recently had the pleasure of reviewing. One of the best chapters is that on the "Kidney and Ureter" (Chap. xxxii); in it the more recent methods of ascertaining the condition of the kidneys, such as catheterisation of the ureters and cryoscopy, are fully gone into. Taking the book as a whole, there are but few statements with which we have to find fault. One such, however, occurs in Chapter xxxi on "The Rectum and Anus," where, in dealing with carcinoma of the rectum, the authors say, "Pain is a variable symptom, but is usually present, and in some cases is agonising." This is a statement which, especially in a book intended for students, we cannot help thinking to be rather unfortunate. We too frequently see carcinomata of the rectum that have reached the inoperable stage, and in which the patient has never suffered pain. If the student has been led to regard pain as a usual symptom, its absence may cause him, as a practitioner, to neglect to make a digital examination of the rectum until the disease has progressed too far for complete removal.

The book concludes with an appendix on anaesthetics. The authors prefer a chloroform and ether mixture, containing one part of the former to two of the latter for children under five and adults over sixty; but in vigorous adults of from eighteen to forty-five they say it is advisable to induce anaesthesia with some other anaesthetic, owing to the risk during the struggling stage.

The illustrations are not so numerous as in the first volume, but the majority are exceedingly good. One could not wish for better illustrations than those showing the various forms of hare lip. We can congratulate the authors on the way they have completed their work. It is one which we can strongly recommend to the practitioner and senior student.

#### DEVELOPMENT AND ANATOMY OF THE PROSTATE GLAND. (b)

THE author, in his preface, states that this is not a

(a) "Manual of Surgery." By Alexis Thomson, M.D., F.R.C.S. Ed., and Alexander Miles, M.D., F.R.C.S. Ed. Vol. II.—Regional Surgery. Illustrated with 156 wood engravings. Pp. 723. Edinburgh: Young J. Pentland, 1904.

(b) "The Development and Anatomy of the Prostate Gland, together with an Account of its Injuries and Diseases, and their Surgical Treatment." By W. G. Richardson, M.B., B.S., F.R.C.S. Pp. 131. 46 Illustrations. London: J. and A. Churchill, 1904. Price, 10s. 6d.

treatise upon the prostate and its diseases, but is an essay which was submitted by him for the Health Scholarship in the University of Durham. The first fifty pages are devoted to a very excellent account of the anatomy and comparative anatomy of the prostate gland. The remainder of the volume consists of a description of chronic enlargement of the prostate, its surgical treatment and the complications following operation, together with a table of thirty-six cases of prostatectomy.

There is no doubt that this essay deserved the prize which was awarded, and we can heartily recommend it to surgeons who are interested in prostatic surgery. The manner of treating the subject is both interesting and instructive. The illustrations are a remarkable feature and very valuable, whilst the publishers deserve great credit for the way in which the book has been turned out.

#### THE PURIN BODIES OF FOODSTUFFS. (c)

THIS work is a re-issue of that given to the medical world in 1902 by Dr. Hall. The previous issue has been revised, partially re-written, the results of recent investigations included, together with new estimations, and the literature on the subject has been brought up to date. A chapter on the action of drugs upon purin excretion is also added.

This work is the result of the desire of Dr. Walker Hall to further investigate "the action of purin bodies and their metabolism, and to discover some means whereby the early pathological changes in certain metabolic disorders may be detected." To effect this, the author first estimated the purin bodies present in some of the commoner articles of food, and then observed their specific effects upon human and animal metabolic processes, when injected subcutaneously, or when introduced *per os*.

Purin bodies, or alloxuric bodies, are substances constructed on the base  $C_5N_4$ , the nucleus  $C_5N_4$  having been termed "purin" by Emil Fischer. The most common purin bodies are hypoxanthin, xanthin, uric acid, guanin, adenin, caffein, and theobromin. Altogether, about twelve of these bodies are known to exist in nature, but 146 have been synthetically prepared in the laboratory. After briefly explaining the composition and properties of the food purins, the author explains the various methods that have been suggested for the extraction and estimation of purins, one of the main difficulties being to find an efficient process for removing the proteids. The author gives a detailed description of the method he employed, and relates the experiments he made to show the accuracy of the process. The quantities of purins in meat foods, vegetable foods, and beverages having been enumerated, he devotes a chapter to the action of food purins on the alimentary and circulatory systems, and also on the respiratory, genito-urinary, nervous, and muscular systems. Dr. Hall then gives us records of experiments, made upon himself and others, to ascertain the comparative effect of purin bodies upon the production of carbon dioxide, and of experiments showing the effect of daily injections of purin bodies in rabbits.

A chapter is devoted to "The Fate of Food Purins in the Body," and one on "The Role of Purin Bodies in Morbid Conditions," where the author shows the necessity for experiments affording information regarding the metabolism of the children of gouty parents and its alterations during their growth. May we hope that many medical men who desire to help forward medical research will assist those workers, like Dr. Hall, who are striving so hard to elucidate the abstruse subject of gout?

The author tersely remarks, when discussing the action of drugs upon the elimination of purin bodies that in gout and allied disorders "Fashion has decreed the use of numerous drugs in the active and prophylactic

(c) "The Purin Bodies of Foodstuffs, and the Role of Uric Acid in Health and Disease." By J. Walker Hall, M.D. Second Edition. Revised. Pp. 201 and xiii, with 29 Tables and Illustrations. London: Sherratt and Hughes, 1903.

lactic treatment of these conditions, and the value of each medicament has been measured in terms of its solvent powers for uric acid in the test tube, quite regardless of the fact that it could not be safely introduced into the blood in sufficient quantities to exercise its soluting properties." The author says that Luff's belief that sodium salicylate is contra-indicated in gout deserves wider appreciation, and, again, "In our present state of knowledge, one fact stands out prominently, *viz.*, that we have not a drug that can be administered in sufficient quantities to affect the circulation of urates in the tissues."

Altogether this book is a straightforward account of the present state of knowledge on the subject of purin bodies, and the author must be congratulated on the comparatively successful issues of his experiments and upon the valuable assistance his work has afforded to medicine; but there are one or two minor details we should like to point out—for example, on page 34, the author is a bit ambiguous. Does he mean that the residue was boiled several times with acidulated water? Again, in describing the estimation of sulphates on page 197, the author omits to say that the barium chloride solution should be added boiling, and also that after that addition the urine containing the precipitate ought to be boiled for fifteen minutes. The above omissions are obviously due to the proof sheets being perhaps hurriedly revised, evidence of which appears several times through the book. Superfluous "ands" occur in two places, an "of" would not be out of place between "excess" and "phosphotungstic" on page 32, Kjeldahne is given for Kjeldahl, stop for stop-cock, nervour for nervous, and, finally, the table of atomic weights, which is so up to date that it includes radium (while excluding sulphur, calcium, and several others), contains four elements spelt in ways that are new to us—*viz.*, borium for boron, molybdium for molybdenum, silica for silicon, and tungstium for tungsten. Lead is also placed among elements commencing with B. The author uses the words "solute" and "soluting" for "dissolve" and "dissolving." There is, however, one serious blunder, and that is on page 197, where we gather that the author incinerates the preparation formed by adding sulphuric acid to the wash water from his barium sulphate-precipitate, together with the latter precipitate. Surely this cannot be what Dr. Hall intends, and multiplying the weight of  $\text{BaO}$  by 0.3433 will give  $\text{SO}_3$ , and not sulphuric acid. Except for the few typographical errors, this little book is admirable in every respect, and we wish the author many further successes in the continuance of his researches on the subject under consideration, and we hope members of the profession will seriously consider the results of Dr. Hall's experiments, they being so vitally important in reference to this all too common disorder.

#### TOLDT ON ANATOMY.(a)

We have received from Messrs. Rebman, Parts IV and V of this most excellent atlas. Part IV deals with the subject of "Splanchnology," and contains nearly three-hundred illustrations to illustrate the anatomy and histology of the various organs of the body. The system of illustrating adopted in former volumes is continued, as a rule with good results. There are special sections devoted to the male and female reproductive organs, and though these are both good so far as they go, we should like the latter to have been more fully dealt with, especially in view of the manner in which it is neglected in most anatomical works. Part V deals with "Angiology," and is, perhaps, the finest part as yet published. It contains something like 200 illustrations, the majority of which are full-page, and, in almost all, the vessels are shown in colours.

(a) "An Atlas of Human Anatomy, for Students and Physicians" by Carl Toldt, M.D., Professor of Anatomy in the University of Vienna, assisted by Professor A. D. Rosa, M.D. Translated from the Third German Edition by M. Eden Paul, M.D. Brux. Fourth Section, Splanchnology. London and New York: Rebman, Limited, 1904.

The illustrations of the pelvic vessels are good but again might be more numerous. The Part concludes with a description of the lymphatic system. The Atlas has well fulfilled the expectations that were formed of it on the appearance of its first part, and we can thoroughly recommend it. One part remains for publication, and will deal with the subject of Neurology and with the Organs of the Senses.

#### BACTERIOLOGY OF MILK. (a)

It was once remarked by a well-known bacteriologist that searching for specific bacteria in milk was like looking for nails in a ten-acre grass field, with the aid of a pair of badly-suited spectacles. Considering that a cubic centimetre of milk may contain over 150,000,000 micro-organisms, this analogy is not exaggerated, and even with the many methods at present at our disposal, the bacteriology of milk is a very difficult matter indeed. The authors of this valuable book, therefore, deserve the hearty thanks of the medical profession, of bacteriologists, of sanitary inspectors, and the public generally. The subject bristles with difficulties, for when we have overcome the difficulty of examining a milk bacteriologically, we are astounded at the great possibilities of danger that may lurk in this important and universal article of diet, and to lessen, if not to prevent, these dangers appears to need stringent legislation. These and many other considerations are ably discussed in this work, which the authors believe to be "the first occasion on which an attempt has been made to deal in a systematic manner with the bacteriology of milk."

As an example of the progress of the subject, take the question of acid-fast bacilli. Not so many years ago we fondly hoped that the Ziehl-Neelsen method of staining excluded all organisms except the *B. tuberculosis*, *B. lepræ*, and the *Smegma bacillus*, but now, thanks to the researches of Koch, Petri, Korn, and others, we find that other organisms have been found in milk and milk products, having originally occurred in the grass, dust, &c., which also retain their colour when stained by this method, and the authors are constrained to insist on "the importance of the inoculation test being applied to all acid-fast and tubercle-like organisms detected in milk or butter." We may remark in passing that the book contains some beautiful coloured plates, illustrating the appearances of growths of these acid-fast bacilli. As at the time this book was published the Royal Commission on Tuberculosis had not issued their interim report, the authors take up the provisional attitude "that tuberculosis in all animals is generically one and the same disease, but that it differs in various ways in different animals, and according to the strain and virulence of the infecting bacillus."

The authors in considering the question of a practical standard of the number of organisms which might be permitted in milk, divide the conditions affecting the number of bacteria into three divisions: The influence of time, the influence of temperature, and the inter-relationship of different species of bacteria and the germicidal effect of the milk. Anyone reading the matter included under the first two headings must be forced to the conclusion that milk ought to be refrigerated as soon as it is drawn. After showing how milk is theoretically an almost ideal medium for both saprophytic and parasitic bacteria, the writers give, on page 20, a table compiled from the experiments of Backhaus, of Königsberg, which shows the possible extent of contamination of milk from various sources in the interval between the milking of the cow and its ingestion by the public.

In the chapter relating to the "Examination of Air and Water in Relation to the Milk Supply," we find

(a) "Bacteriology of Milk." By Harold Swithinbank and George Newman, M.D., F.R.S.E., D.P.H. With special chapters, also by Dr. Newman, on the Spread of Disease by Milk and the Control of the Milk Supply. With 83 plates, 35 text illustrations, and 4 maps and charts. Pp. 606 and xx. Price 25s. net. London: John Murray, 1903.

one or two little details in which we must differ from the authors. Many people will disagree with the statement that "*B. coli* is a most accurate measure of intestinal pollution," and an enumeration of this bacillus is certainly a wearisome and unsatisfactory way of judging the extent of pollution. A note to the effect that a partial chemical examination of the water would be most valuable, probably more so than the tedious bacteriological examination, would not perhaps be out of place. We might venture to point out that the percentage of salts in milk given on page 4, *viz.*, 0.7, is lower than it should be, *viz.*, not lower than 0.75.

Twenty appendices dealing with Acts affecting milk, regulations in force in private companies and in various districts and on kindred subjects, close a volume which is well illustrated, well written, singularly free from errors, and which must be considered, in the present state of our knowledge, the standard book on the subject.

#### REPORT OF THE REGISTRAR-GENERAL, IRELAND. (a)

THE concentrated information contained in the summaries compiled for the pages of this "Supplement" makes it, of course, a most interesting and instructive volume of reference. The causes of death which have been most profusely discussed of recent years in this country are, we believe, *alcoholism*, *cancer*, and *phthisis*. On this account the following extracts will be of the greatest interest to all readers:—(1) "During the decade, 1,601 deaths were attributed to the effects of alcohol; of these 1,601 persons, 1,306 were males and 295 were females. Of the total deaths, 421 were registered as having been caused by delirium tremens (388 males and 33 females); and 1,180 persons fell victims to chronic alcoholism (318 males and 262 females)." (2) "According to the system which obtained during the ten years now the subject of review, the deaths classified under the head of cancer, malignant disease, include those deaths which were certified as carcinoma, scirrhus, epithelioma, rodent ulcer, &c., and sarcoma. The total number of these deaths recorded in the decade is 24,435, of which 11,062 were of males and 13,373 were of females. In the preceding decade the number of deaths from cancer in Ireland was 20,036, *viz.*, 8,964 males and 11,072 females, and in the decade which ended with the year 1880, the total number of deaths recorded was 17,790 (7,789 males, and 10,001 females). The average annual rate per 10,000 of the population represented by the deaths from cancer, malignant disease, which for the decade 1871-80, was 3.4 per 10,000 of the mean population, rose to 4.1 for the following ten years, and to 5.3 for the decennium ending with the year 1900. . . . The deaths of 11,062 males and 13,373 females were recorded, these numbers are equal respectively to the average annual rate of 4.90 and 5.76 per 10,000 of the mean population of males and females in Ireland." Omitting the cases under 25 years of age registered as deaths from cancer, "only 294 (156 males and 138 females) during the decennium," . . . "and basing the calculations on the estimated mean number of persons aged 25 years and upwards in the population, it is found that the deaths from cancer and malignant disease during the decade were equal to an average rate of 11.1 per 10,000 persons, against an average rate of 8.8 per 10,000 for the preceding ten years, and a rate of 7.3 per 10,000 for the ten years 1871-80, so that in the ten years 1891-1900, allowing for the decrease in the population, the registered mortality under the head of persons aged 20 years and upwards was 52 per cent. in excess of that for the ten years 1871-80, and 26 per cent. in excess of that for the decade 1881-90. The average rates for the sexes taken separately were: In ten years ending with 1880, males 6.7 per 10,000

(a) "Supplement to the Thirty-seventh Report of the Registrar-General of Marriages, Births, and Deaths in Ireland, containing Decennial Summaries of the Returns of Marriages, Births, Deaths and Causes of Death in Ireland for the years 1891-1900." Dublin: E. Ponsonby; London: Eyre and Spottiswoode; Edinburgh: Oliver and Boyd. 1904.

males aged 25 years and upwards in the population: females 7.8 per 10,000; in the ten years 1881-90 males 8.2, females 9.3; and in the decade 1891-1900 males 10.4, females 11.7 per 10,000." (3) "In the classification followed during the decade 1891-1900 deaths from tuberculosis were distributed under four heads, namely, 'Phthisis,' 'Tuberculous Meningitis (acute hydrocephalus), 'Tabes Mesenterica,' and 'Other Forms of Tuberculosis. Scrofula.' . . . The tuberculous death-rate has risen in Ireland since the first of the decades [1871-80] covered by the above statement—a fact which goes to show that the sanitary and other measures which have been undertaken for the improvement of the public health have not as yet arrested the ravages of this formidable disease." These extracts form ample proof that there is full scope for the future labours of the moralist, the sanitarian, and the therapist in the opening era of the democratic section of Irish history.

#### PARLIAMENTARY REPRESENTATION OF THE UNIVERSITIES OF GLASGOW AND ABERDEEN

AT a meeting of the Graduates of the above Universities held at the Holborn Restaurant, London, on Thursday, the 8th inst., the Rev. Canon D. Reith, M.A. in the chair, to hear an address from Professor William R. Smith, M.D., it was subsequently moved by Mr. T. B. Browning, M.A., seconded by Dr. J. Nelson Matthews, and carried, "That this meeting of graduates of Glasgow and Aberdeen Universities cordially endorse the candidature of Prof. William R. Smith, M.D., and pledge itself to use its best endeavours to secure his return." In supporting the resolution, Prof. W. J. Simpson, M.D., F.R.C.P., and Dr. J. Ford Anderson pointed out the totally inadequate representation of the Medical profession in Parliament, that this seat offered one of the very few of the opportunities for returning a medical man to Parliament, and the difficulty always experienced in finding a medical candidate; they insisted upon the reflection which would be cast upon the graduates if they had to seek a representative from another University as was suggested, and urged that in Professor Smith, who had attained a prominent position in Preventive Medicine and had great public experience, they had a candidate whom it was most desirable should be elected. Meetings of the medical graduates have also been held in Sheffield, Blackburn, and Lincoln, at which a similar resolution was passed.

#### Medical News.

##### The London Polyclinic Dinner.

THE sixth annual dinner of the London Polyclinic was held on the 7th instant at the Trocadero Restaurant under the genial presidency of Dr. C. Theodore Williams. It was announced that Mr. Jonathan Hutchinson, one of the founders of this flourishing and valuable institution, was unfortunately unable to be present on account of indisposition. Another founder was present, however, in the person of Dr. Fletcher Little. A large company, including many ladies, appeared to enter thoroughly into the swing of a capital evening's entertainment. Dr. Theodore Williams made a capital speech. Among other things he spoke of the post-graduate courses that formerly sent the student all over London in search of hospitals for this, that, and the other speciality, until he arrived finally at Bedlam in an exhausted condition and more fitted to be an inmate than a mere visitor. Captain Haward Punch, the energetic secretary, delivered an amusing and apposite speech. Mr. Mayo Robson responded for the Polyclinic and Mrs. Scharlieb for "The Ladies." Several speakers dwelt on the present state of affairs in this undertaking as most promising of future prosperity.

##### Liverpool School of Tropical Medicine.

LAST week a deputation from the Liverpool School of Tropical Medicine waited on the Colonial Secretary, Mr. Lyttelton, for the purpose of bringing before his notice the despatch of a large medical and scientific expedition to West Africa for the purpose of helping

to promote the work of stamping out tropical diseases. Sir Alfred L. Jones introduced the deputation, which consisted of the following gentlemen:—Professor Boyce, F.R.S., Sir Ralph Moor, K.C.M.G., Colonel Giles (India Medical Service), Dr. Evans, Dr. M'Connell (Canada), Dr. Jollerton Thomas (Canada), Dr. Anton Baniel (Austria), Dr. Clarke, and Mr. A. H. Milne (hon. secretary, Liverpool Tropical School), Mr. John Holt, Mr. J. Irvine, Mr. J. Strafford, Mr. Haggart, and Mr. B. Caarten.

#### Heavy Damages for Assault on a Medical Man.

DR. A. D. GRIFFITHS was last week awarded £500 damages at Swansea yesterday for an assault committed by George Faithfull, an electrician, while Dr. Griffiths was attending the defendant's wife. The assault was aggravated by a charge reflecting on the doctor's character.

#### Sympathy with Dr. Arthur Griffiths, Bridgend.

At a largely-attended meeting of the South Wales and Monmouthshire Branch of the British Medical Association, held at Carmarthen, the following resolution was unanimously passed:—"That the members of the South Wales and Monmouthshire Branch of the British Medical Association desire to convey to Dr. Arthur Griffiths their sincere sympathy with him in the painful position in which he was recently placed by the unfounded charge laid against him, and their congratulations on his having so completely justified their trust in his unblemished character." This motion was proposed in the name of the President of the Branch by Mr. Tatham Thompson (Cardiff), seconded by Dr. Evan Jones (Aberdare), and supported by Dr. Cresswell (Dowlais) and Dr. Lynn Thomas (Cardiff).

#### Nottingham Medico-Chirurgical Society.

THE Nottingham Medico-Chirurgical Society held its annual dinner at the George Hotel, last week, under the presidency of Dr. H. J. Neilson. The Mayor of the City (Alderman Joseph Bright) was the guest of the evening, and Councillor Dr. T. J. Daybell attended in a dual capacity as Sheriff, and as a member of the organisation, the company numbering about 70. The toast of "The Society" was submitted by the President of the Leicester Medical Society (Dr. R. C. Stewart), and acknowledged by the President. The Vice-President (Dr. J. F. Blurton) proposed "The Visitors and the Mayor of Nottingham," and "The President of the Derby Medical Society" (Dr. F. R. Cassidy).

#### Trinity College, Dublin.

THE following candidates passed the Final Examination in Midwifery:—Benjamin Johnson, Arthur A. M'Neight, John Cunningham, Lily A. Baker, William J. Powell, William R. Galwey and William Nunan (equal), Thomas J. T. Wilmot, Eva J. Jellett, James H. C. Thompson, Henry E. M'Creedy, Thomas Creaser, George McG. Millar, William Hassard, Carlile Kelly, and Alfred G. Alexander.

#### Chemists' Exhibition.

COVENT Garden Theatre has been selected as the site for the next annual Chemists' Exhibition, organised by the *British and Colonial Druggist*. The same building, it may be remembered, was used for the exhibition some seven years ago. The Exhibition will be open from March 13th, 1905, to March 17th, inclusive.

#### Hospital Sunday Fund.

THE annual general meeting of the Metropolitan Hospital Sunday Fund will be held at the Mansion House on Friday next at 2.30.

#### Royal College of Surgeons of England.

At the ordinary meeting of the Council of the College held on Thursday last, Mr. John Tweedy, F.R.C.S., President, in the Chair, the death of Professor Tillaux of Paris, an honorary Fellow of the College was reported. Diplomas of Fellowship were issued to 29 candidates, and diplomas in Dental Surgery to 40 candidates. In accordance with the recommendation of the Board of Examiners in Dental Surgery, it was decided to publish a syllabus defining the scope of the examination in anatomy, physiology, and surgery which candidates

for the licence in Dental surgery are required to pass. It was also decided that this examination should be held three times instead of twice during the year. In reference to a communication from the Board of Education asking the opinion of the College upon proposals framed by the consultative committee of the Board for a system of school certificates, a resolution was adopted expressing general approval of the scheme. Mr. Bernard Pitts, F.R.C.S., surgeon to St. Thomas's Hospital, was re-elected a member of the Court of Examiners. The resolutions carried at the annual meeting of Fellows and Members on the 17th ultimo were reported to the Council. The Liverpool Stanley Hospital was added to the list of General Hospitals recognised for the purposes of study by candidates for the Diploma of the college. It was also determined to add the Municipal College, Grimsby, to the list of institutions recognised for instruction in chemistry, physics, and practical chemistry. A report was received from the laboratories committee stating that, during the three months ending December 1st, 7,548 doses of diphtheria antitoxin, each containing 3,000 units, have been supplied to the hospitals of the Metropolitan Asylums Board.

THE following members of the Royal College of Surgeons of England were admitted to the Fellowship of the College at the meeting of the Council on the 8th instant, Mr. John Tweedy, the president, in the chair:—John Arthur Hayward, M.D. London, St. Bartholomew's and Oxford; Cecil Edward Marriott, M.B. Cambridge, Cambridge and University College, London; Francis Joseph Maria Hasslacher, M.B. London, King's College, London; John Clay, M.B. Durham, Durham; Herbert Dean Pollard, M.B. London, London; Donald Johnstone McGavin, M.D. London, Birmingham and London; Charles Ferrier Walters, L.R.C.P. London, Bristol; Reginald Cheyne Elmslie, M.B. London, St. Bartholomew's; George Ernest Waugh, M.B. London, Cambridge and University College, London; William Francis Harriott Coke, L.R.C.P. London, St. George's; Ernest Rock Carling, M.B. London, Westminster; Somerville Hastings, M.B. London, Middlesex; Hugh Davies-Colley, M.B. Cambridge, Cambridge and Guy's; Harold Upcott, L.R.C.P. London, St. Thomas's; Joseph Ebenezer Adams, L.R.C.P. London, St. Thomas's; Harold Ashton Lyth, M.B. London, University College; London; William Arthur Rees, M.B. London, Middlesex; Arthur Robertson Brailey, L.R.C.P. London, Cambridge and Guy's; Norman Carpmael, L.R.C.P. London, St. Thomas's; Charles Bernard Goulden, M.B. Cambridge, Cambridge and Middlesex; Walter Lidwel Harnett, M.B. Cambridge, Cambridge and St. Thomas's; Archibald Trevor Moon, L.R.C.P. London, London; Kenneth Black, L.R.C.P. London, Guy's; Thomas Jefferson Faulder, L.R.C.P. London, Cambridge and St. Bartholomew's; Neville Ivens Spriggs, M.B. London, Guy's; Frederick Henry Parker, M.B. Cambridge, Cambridge and Guy's. The following, not being members of the College, were also admitted Fellows: Robert James Ferguson, M.D.R.U.I., Belfast; Angus McNab, M.B. Edinburgh, New Zealand and Edinburgh; Herbert Bell Tawse, M.B. Aberdeen, Aberdeen and King's College, London.

ON Saturday, the 10th instant, the employés of the united firms of Messrs. Odhams Limited, and Southwood, Smith and Co., Limited, gave their annual dinner at the King's Hall, Holborn Restaurant, London. Some capital speeches were made by the Chairman, W. J. B. Odhams, Esq., and Messrs. Elias, Moir, Lathbury, and Filson Young. The proceedings were varied with an excellent programme of glees and songs. Our readers will be familiar with the name of Odhams Limited, as printers of the *MEDICAL PRESS AND CIRCULAR* for many years past.

THE annual meeting of the Dublin branch of the National Association for the Prevention of Tuberculosis will be held in the Royal College of Physicians this afternoon (Wednesday) at 4.30 p.m.

## Notices to Correspondents, Short Letters, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

**ORIGINAL ARTICLES** or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

**CORRECTORS** are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to offices, these should be addressed to the Publisher.

**REPRINTS.**—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

**DR. SCHREIB (Algiers).**—Will receive a private note.

### INSOMNIA.

**Visitor:** And what is your husband's complaint, Mrs. Green? **Mrs. Green:** The doctor says it's Insomnia, ma'am; but Bill thinks if 'e could only sleep o' nights 'e'd get over it.

### IN THE APPENDIX.

At a recent dinner the following story was told: "At the same time of King Edward's recovery from appendicitis, thanksgiving services were held all over the British dominions. The services were concluded at a certain church by the singing of a well-known hymn, which happened to be in the back portion of the book. 'Let us close the service,' the rector said, 'by singing the hymn, 'Peace Perfect Peace—in the appendix.'"*—Texas Medical News.*

**KIDDERMINSTER.**—A proper apparatus is needed to prepare instruments and dressings for surgical use on a large scale. Any competent practitioner, however, who is well-grounded in the principles of aseptic surgery, can do all the sterilising wanted for an occasional surgical operation by extempore methods. A small saucopan will serve to sterilise a scalpel, a pair of scissors, dressing forceps, pressure forceps, and needles and thread. With this simple means and some wool pads that can be bought ready sterilised, a capable man could achieve a great deal of operative work.

**DR. E. KINNSOCK (Vienna).**—Your paper on the "Clinical Value of Radiography in Traumatic Intra-muscular Osteomys" is in hand, and will be published as soon as the necessary illustrations are ready.

**H.E.B. (Liverpool),** is thanked, but the paper is scarcely suitable for our columns.

**DR. WOSSIDLO (Berlin).**—Your paper on the "Development of Diagnosis and Treatment of Urinary Diseases" has been received and is marked for early insertion.

**SALUS POPULI.**—The Medical Officer of Health of the District is undoubtedly the man to whom your patient should apply. If, as unfortunately happens in country districts, he is a rival practitioner, that fact should not be allowed to hinder or affect the discharge of his official sanitary duties. A more desirable state of things would be to discover the functions of Medical Officer of Health and of private practitioner, as the two are incongruous and, as a rule, incompatible.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, DECEMBER 14th.

**SOUTH-WEST LONDON MEDICAL SOCIETY** (Bollingbroke Hospital, Wandsworth Common).—8.45 p.m. Paper: Dr. S. Taylor: Errors of Treatment.

**DERMATOLOGICAL SOCIETY OF LONDON** (11 Chandos Street, Cavendish Square, W.).—8.15 p.m. Demonstration of Cases of Interest.

**HUNTERIAN SOCIETY** (London Institution, Finsbury Circus, E.C.)—8.30 p.m. Paper: Dr. G. E. Herman: Leucorrhoea.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Q. Silcock: Clinique. (Surgical.) 5.15 p.m. Dr. L. Guthrie: Mental Overstrain in Childhood.

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—5 p.m. Demonstration:—Dr. Abercrombie: Nose.

THURSDAY, DECEMBER 15th.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chancery Street, W.C.).—4 p.m. Mr. Hutchinson: Clinique. (Surgical.) 5.15 p.m. Dr. L. Guthrie: Mental Overstrain in Childhood.

**MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST** (7 Fitzroy Square, W.).—5 p.m. Lecture: Mr. H. Barwell: Laryngeal Tuberculosis: its Treatment and Prognosis (Demonstration of cases). (Post-Graduate Course.)

FRIDAY, DECEMBER 16th.

**SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN** (12 Chandos Street, W.).—8.30 p.m. Discussion on Sudden and Unexpected Death in Children (opened by Dr. C. J. Macallister, Liverpool). Dr. J. P. Parkinson, Mr. J. W. Thomson, Mr. A. H. Tubby, and Dr. J. Blumfeld will take part in the Discussion.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture-Demonstration:—Mr. de Frenerville: Anaesthetics.

TUESDAY, DECEMBER 20th.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE** (Tottenham Hospital, N.).—4.30 p.m. Lecture-Demonstration: Mr. de Frenerville: Anaesthetics.

**THERAPEUTICAL SOCIETY** (Apothecaries Hall, E.C.).—4 p.m. Dr. Neslor Tirard: On Some Clinical Observations with new Kamodia. The Secretary will read a paper by John B. Gimlette called "Notes on some Methods employed by Kelantan Malays in the Treatment of Furu or Yaws."

## Vacancies.

**Nottingham General Hospital.**—Assistant House Physician. Salary £100 per annum, with board, lodging, and washing in the Hospital. Applications to E. M. Keely, Secretary.

**Nottingham General Hospital.**—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing in the Hospital. Applications to E. M. Keely, Secretary.

**Whitehaven and West Cumberland Infirmary.**—Resident Home Surgeon. Salary £120 per annum, with board and lodging. Applications to Wm. H. Sands, Secretary.

**Cumberland and Westmorland Asylum, Garlands, Carlisle.**—Junior Assistant Medical Officer.—Salary £130 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

**West Sussex County Asylum, Graylingwell, Chichester.**—Junior Assistant Medical Officer. Salary £ 50 per annum, with furnished apartments, board, attendance, &c. Applications to the Medical Superintendent.

**Nottingham City Workhouse Infirmary.**—Junior Resident Medical Officer. Salary £120 per annum, with apartments, board, washing and attendance. Applications to G. Muncester Howdell, Clerk to the Board, Poor-law Offices, Nottingham.

**Jaffray Branch of the General Hospital Gravelly Hill, near Birmingham.**—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence and washing. Applications to the House-Governor, General Hospital, Birmingham.

## Appointments.

**BANNERMAN, WILLIAM, M.B., C.M. Edin.,** Medical Officer and Public

Vaccinator for the North District of the Cirencester Union.

**CARLE FREDERICK C., M.B. Lond., M.R.C.S.,** Senior Clinical Assistant

to the Throat Hospital, Golden Square, W.

**DAVIES, D. L., M.B., B.S. Lond.,** Certifying Surgeon under the Factory Act for the Wisbech and Walsoken District of the counties of Cambridge and Norfolk.

**DAY, LEIGH, M.B., B.Ch. Oxon.,** Honorary Assistant Surgeon to the Essex and Colchester Hospital.

**DELANEY, K., L.R.C.P.I., L.R.C.S.I.,** Certifying Surgeon under the Factory Act for the Carrick-on-Shannon District of the County of Leitrim.

**DIETMAR, F., M.D. Glasg., D.P.H. Cantab.,** Medical Inspector of the Local Government Board of Scotland.

**EWART, E. W. T., M.B., C.M. Edin.,** Clinical Assistant to the Chelsea Hospital for Women.

**FARQUHARSON, J. MALCOLM, M.B., F.R.C.P. Edin.,** Second Assistant Surgeon to the Ear, Nose, and Throat Department of the Royal Infirmary, Edinburgh.

**HALL, DONALD G., M.A., M.D. Cantab., M.R.C.P. Lond.,** Assistant Physician to the Sussex County Hospital, Brighton.

**JONES, EDWARD T., M.R.C.S. Eng.,** Medical Officer of Health of the Borough of Helston, Cornwall: Medical Officer to the Workhouse and to the No. 1 District, and Public Vaccinator.

**MACLAREN, NORMAN, B.C. Cantab., F.R.C.S. Eng.,** Assistant Surgeon to the Cumberland Infirmary.

**ROGERS, J., L.R.C.P.I.,** Certifying Surgeon under the Factory Act for the Ballyarnon District of the county of Sligo.

**SHAW, W. F. M.B., Ch.B. vict.,** House Surgeon and Resident Obstetric Assistant Surgeon to St. Mary's Hospital, Manchester.

**TENCH, M., M.R.C.S., L.R.C.P. Lond.,** Certifying Surgeon under the Factory Act for the Dunmow District of the county of Essex.

## Births.

**ADDISON.**—On December 8th, at Wican Croft, Northwood, Middlesex, the wife of Christopher Addison, M.D., of a son.

**PENNINGTON.**—On December 8th, at Cariton House, Argyll Road, West Ealing, W., the wife of S. B. Pennington, M.R.C.I., L.R.C.P., of a daughter.

**REYNOLDS.**—On December 9th, at Highercroft, Shepherd's Hill, Highgate, N., the wife of Austin Edward Reynolds, M.R.C.S. Eng., of a son.

## Marriages.

**PHILLIPS—COXON.**—On December 7th, at Hampstead Parish Church, Llewellyn Powell Phillips, M.A., M.D. Camb., M.R.C.S., M.R.C.P. of Kasr-el Ain Hospital, and the School of Medicine, Cairo, Egypt, only son of the late Dr. Jam's Mathias Phillips, of Oxford, to Edith Helen, daughter of the late Alfred Coxon and of Mrs. Coxon, Grindon House, Surbiton.

## Deaths.

**LUSH.**—On December 7th at Dorchester, suddenly whilst attending a meeting at the Dorset County Hospital, William George Vandrey Lush, M.D., F.R.C.S. Lond., F.R.C.S. Eng., of No. 12 Frederick Place, Weymouth.

### ADENOMA HÆMORRHAGICA OF THE ENDOMETRIUM. (a)

By WILLIAM ALEXANDER, M.D., F.R.C.S.,  
Honorary Surgeon, Royal Southern Hospital, Liverpool, &c.

It is very strange how frequently students of medicine have to search in vain for assistance from books in regard to conditions that they meet with in their practice, conditions that they have seen with comparative frequency, and that have apparently been overlooked by other observers, or if seen have not been considered of sufficient interest to secure a record. Some conditions seem to be recorded too frequently, others are perhaps mentioned by some old writer, but not a modern one is raised to rescue them from obscurity. Such are the cases I bring before you to-night in the hope that I may obtain more information than I have been able to derive from books:—

CASE I.—In 1899, a lady, æt. 34, consulted me for metrorrhagia of eighteen years' duration. During none of these years she had no bleeding, not even at menstruation. This year of freedom was early in the disease. Like the lady in Scripture, she had consulted many physicians without lasting benefit. She had been cured by an eminent gynecologist, now dead, but the relief was only for two months, when the metrorrhagia appeared as before. She was frequently bed-ridden, and at all times a useless invalid, although she had strong aspirations after a useful and busy life. Oöphorectomy had been recommended quite recently. This she felt inclined to have performed, but her medical attendant on hearing of the proposal warned her against it, telling her that removal of the ovaries was frequently allowed by insanity. Such a possible, or rather probable, result naturally frightened her, and she reluctantly refused that operation, resumed her couch, her bed, and her ergot, without much hope of ever being cured, and with the prospect of spending her life, up to the menopause at any rate, as an invalid under medical supervision. She knew all about it, having had a large experience of medical men and medical subjects. Finding that after a more prolonged trial such a life was intolerable, she, without consulting either her doctor or her relatives, came to the out-patient gynecological clinic at the Royal Southern Hospital. The patient was fairly nourished, but pallid and flabby, the result of repeated hæmorrhages and of her sedentary life. To walk or even slight movements about her room would, he said, bring on the bleeding, and sometimes she had to remain in bed altogether for days. The uterus was slightly enlarged and congested, but there was no sign of malignant disease, and the patient's age did not favour such a serious diagnosis. There were no palpable broids, although the existence of small fibroids was the diagnosis arrived at. The previous history of the disease and its treatment did not permit the hope that

further curetting would be more permanently successful than before, and her wish was to have the bleeding stopped, at any cost but that of her sanity and her life. She had no intention of marrying, but wished to live an active, useful life, and did not mind the loss of any of the child-bearing organs. She was advised to have a vaginal hysterectomy performed. This operation, she was told, was certain to stop the metrorrhagia, and, the ovaries being left behind, was not likely to produce such serious symptoms as were alleged to follow oöphorectomy. After consulting with her friends, she came into the private ward of the Royal Southern Hospital; hysterectomy was successfully performed on July 6th, 1899, and the patient left the hospital well on August 8th, 1899. On opening up the uterus after its removal, we found the mucous membrane replaced by a soft, white, gelatinous-looking substance about one-sixth of an inch thick, spreading up into the Fallopian tubes on each side, where it was specially luxuriant and almost polypoid, becoming scanty below and not so even on the surface. It looked as if the growth was reforming below after having been torn away there by the curette. The uterine walls seemed normal, and there was no induration.

Photograph of interior of Uterus in Case I.

CASE II.—In 1900, a Miss G., æt. 39, was seen by me with Dr. George Johnston, of Liverpool, on account of persistent and profuse metrorrhagia extending over eight years. She was very anæmic, but did not seem to have lost much flesh. She had been curetted about five years ago, not only without lasting benefit, but she said the hæmorrhage had been worse since the curetting. I performed the curetting myself most carefully and thoroughly. Her family history was distinctly phthisical, and the dread of the onset of phthisis that possessed the minds of her relatives and of her medical

(a) Read at a meeting of the British Gynecological Society December 8th, 1904.

attendant was naturally intensified by the hæmorrhage, especially as she had been losing weight. I described my experience with the former case, and the same treatment was readily agreed to both by the patient and her friends, and by Dr. Johnston. On April 5th, 1900, vaginal hysterectomy was performed. The uterus presented exactly the same appearance as in the previous case. The results of the operation were all that could be desired, the anæmia was gradually recovered from, and no signs of phthisis have so far appeared.

Photograph of interior of uterus in Case II.

CASE III.—Miss C., æt. 38, single, had been quite regular and normal as regards menstruation up to five years ago, when she became the subject of frequent uterine hæmorrhages at all times, and sometimes to a great extent. The hæmorrhage was checked at first by ergot. When this failed, curetting was performed, and the hæmorrhage abated for a few months. It then came on again more vigorously than ever, and in the meantime one sister had died from recurrent cancer of the breast, and the second had been recently operated upon for the same disease. The patient was also the subject of a nervous twitching of the muscles of the head and neck, which was made much worse by the hæmorrhage. Marriage and child-bearing were not likely events. She was in the meantime much reduced by the repeated losses of blood. From every point of view it seemed to be desirable to have the uterus removed. This was done on September 18th, 1900. The ovaries were left behind. The patient is now (1904) in excellent health. The uterus presented the same appearance as the other cases.

Photograph of interior of uterus in Case III.

CASE IV.—Mrs. H., æt. 36, married, one child sixteen years ago, from the birth of which she recovered satisfactorily. Ten years ago she had an ovarian tumour removed, and soon afterwards began to suffer from leucorrhœa and occasional metrorrhagia. Neither of these symptoms ever became severe, but they persisted in spite of treatment of different kinds. Twelve months ago she began to suffer pain in the right side of the pelvis, which continued ever since uninfluenced by any drugs, except sedatives. Six months ago dyspareunia set in, and was accompanied by blood-stained, foul-smelling discharge. Patient is cachectic-looking. On examination, the os uteri was found elongated, eroded, and very hard, but not apparently the seat of malignant disease. The canal of the uterus was normal in depth. Microscopical examinations of curettings did not give a decided diagnosis of any kind. Clinically the disease looked so malignant in its nature that removal of the uterus was advised, and was readily agreed to both by the patient and her husband. The operation was performed on November 3rd, 1904. On cutting the uterus open, the pathologist remarked, "The whole endometrium was infiltrated with a whitish fibrous-looking formation that merely thickened the walls of the uterus without altering their contour." It was an exact counterpart of the conditions found in the other cases. On November 29th the patient was discharged, quite well.

CASE V.—Emily E., æt. 41, admitted to hospital November 13th, 1903. She was confined eighteen months ago. Soon after convalescence from the confinement she began to suffer from pain in the lower part of the abdomen and back, and from intermittent attacks of bleeding, which were not amenable to treatment. Two days before admission she had severe hæmorrhage, and was bleeding profusely when admitted to hospital. Ergot was given, and the hæmorrhage stopped. Examination showed an enlarged, eroded anterior os, uterine cavity normal in size. A curetting did not show any growth or irregularity of the uterine wall. As the state of the os was considered suspicious, a small piece of the anterior lip was removed for examination, and a section showed dense fibrous tissue with cystic dilatation of the cervical glands. No evidence of malignancy. She was douched with creolin. Ergot and hydrastis were prescribed. The hæmorrhage continued, and was frequently accompanied by so much pain that nepenthe had to be resorted to. On December 16th, 1903, the os was dilated up to 22, and the cavity thoroughly curetted. The pathologist did not make anything definite out of the curettings, except that the glandular tissue was increased. For a few days she was relieved, when the hæmorrhage began again, and continued at frequent intervals. On January 21st, she had a severe attack of metrorrhagia, accompanied by severe pain in the pelvis. She was evidently losing ground so rapidly that, being convinced that the disease was probably malignant, I advised vaginal hysterectomy, which was performed on January 25th, 1904. The patient made a good recovery, but some troublesome pains in her back continued more or less till May, when she reported herself as quite well. She has not been seen since. The uterine cavity presented an exactly similar appearance to the previous two cases, where a fine, soft gelatinous substance was spread over the surface of the uterine cavity.

It will be seen that the chief symptom in all these cases was persistent hæmorrhage recurring after curetting and after all treatment; not so great as to destroy life, but sufficient to keep up a condition of anæmia and invalidism. The size or shape of the uterus did not differ materially from that of a normal uterus, and the curettings did not present to the pathologist anything abnormal. The glands were, perhaps, more numerous, but nothing more. One had a child sixteen years ago, and another had a child one year and a half ago; the rest were all nulliparous women.

After removal, the uterine cavity presented very distinct and uniform features in a thick, semi-gelatinous, semi-fibrous membrane, running into folds or polypoid masses affecting the whole mucous membrane of the uterus and the beginnings of the Fallopian tubes. Little points of blood appeared here and there in some of the specimens. I am sorry not to be able to show a recent specimen, as hardened specimens become quite different in appearance. I can, however, show slides which will give some idea of the appearance of recent cases.

I have only recently had Case IV. thoroughly examined by Dr. F. Griffith, one of the pathological Fellows at the Thompson Yates Laboratories, Liverpool. He reports the disease to be an adenoma of the endometrium, and the two photo-microscopic lantern slides he has prepared for me will show you at a glance the nature of the change. You will then see how the glandular

Microphotographs showing downgrowths of epithelium.

tissue has dipped down between the bundles of muscular fibres of the wall of the uterus, and it is probably the presence of these downgrowths of adenomatous tissue that produces the hæmorrhage, and hence the disease.

Hysterectomy was successful in all these cases, and a cure resulted in them all. That resource is only to be had recourse to when all well-known methods have failed, and when sufficient time has elapsed. Eighteen years is, however, too large a slice out of a human life to let pass before using curative means.

### A NOTE UPON SOME SUBSTITUTES FOR SILVER NITRATE IN EYE WORK, WITH PARTICULAR REFERENCE TO ARGYROL.

By SYDNEY STEPHENSON, M.B., C.M.,

Editor of the *Ophthalmoscope*, &c., &c.

NITRATE of silver (or lunar caustic, as it used to be called) has enjoyed for nearly two hundred years a reputation in the treatment of superficial affections of the eye. Its value was recognised by the older writers. For example, Saint-Yves certainly used and recommended silver in the earlier years of the eighteenth century. V. Graefe, in 1826, was using a solution of the nitrate, ten grains to the ounce. In 1830, Velpeau adopted silver in inflammations of the eye. Gouzzé, a Belgian surgeon, in 1839 warmly advocated a concentrated solution of the caustic for the treatment of a disease then known as the "Egyptian ophthalmia," commonly but erroneously supposed to have been introduced into Europe by the return of the French troops from Napoleon's Egyptian and other campaigns. Guthrie, of the Royal Westminster Ophthalmic Hospital, London, treated trachoma by an ointment which contained about eighty grains of the finely pulverised silver salt to an ounce of hog's fat. This preparation, commonly known as Guthrie's "Black Ointment," or more pedantically as the "Unguentum ophthalmicum magicum," was applied directly to the conjunctiva by means of a brush, and the application was repeated daily. Graphic accounts are upon record of the sufferings caused to patients by this somewhat heroic, although doubtless efficacious, agent. In 1842, Desmarres ("Mémoire sur une nouvelle méthode d'employer le nitrate d'argent dans quelques ophtalmies," Paris, 1852) described a new application of silver nitrate. He clearly distinguished between the astringent and the caustic effects of the remedy, which he employed as a solution containing 40 to 90 centigrammes in ten grammes of water, dropped into the eye every half-hour for forty-eight hours. William Mackenzie in his classical "Practical Treatise" (1854) describes the action of the silver in catarrhal ophthalmia in the following graphic words:—"I have sometimes alarmed other practitioners," wrote Mackenzie, "by proposing to drop upon the surface of an eye highly vascular, affected with a feeling as if broken pieces of glass were rolling under the eyelids, and evidently secreting puriform matter, a solution of lunar caustic; and I have been," he continues, "not a little pleased and amused at their surprise when, next day, they have found all the symptoms much abated by the use of this application." A treatment for so-called "strumous" inflammation of the conjunctiva and cornea that had a large vogue at about this time consisted in applying solid silver stick to the palpebral conjunctiva. It is a somewhat curious coincidence that an identical treatment has been recommended this year by Schiele (*Woch. f. Therapie u. Hygiene des Auges*, September 8th and 15th, 1904).

The employment of silver nitrate was extended by the encomiums of that great master of ophthalmology, Von Graefe, and popularised by the recommendations of Scarpa, Arlt, and others.

Nitrate of silver, then, reigned supreme in the treatment of superficial eye diseases until comparatively recently. That it possessed disadvantages was recognised even by its most strenuous advocates, but it was generally felt that these were more than outweighed by its potent escharotic, astringent, and

antiseptic properties. It was admitted on all sides that the remedy called for no little experience in its application; that much pain was often caused; that it might destroy tissue if used carelessly; that it did not penetrate deeply owing to insoluble compounds formed with albuminoids; and, finally, that its long-continued use was liable to produce an indelible staining of the tissues, as the conjunctiva and the cornea, with which it was brought into contact. William White Cooper perhaps summed up the position when he wrote:—"But the nitrate of silver is the most frequent agent of mischief; powerful for good if used with judgment, it is all-powerful for evil if misused" ("On Wounds and Injuries of the Eye," London, 1859, p. 290).

Of the caustic effects of silver nitrate I have personally witnessed several deplorable examples. In one case a nurse applied to the palpebral conjunctiva a concentrated solution of the salt, with the result that the conjunctiva became sloughy and ulceration of the cornea was set up. The patient made a slow recovery, but with scarred conjunctiva and defective sight, due to the corneal cicatrices. In another case a woman had had a rectus muscle advanced for the correction of a divergent squint. A fortnight or so after the operation, a small button of granulation tissue was found to be growing from the site of operation. It was determined to cauterise the little growth. Accordingly, a stick of silver nitrate, fixed in a goose-quill holder, was held under a stream of water for a moment for the purpose of freeing it from some impurity. It was then used to touch the excrescence. The front of the eye, including the cornea, at once became covered and hidden by a whitish film, which, under the influence of the bright sun shining into the room, turned black in a few moments, so that the eye presented a horrifying appearance. The explanation of the untoward circumstances was simple. Water had remained in the quill above the silver point, and when the eye was touched with the stick, the parts were immediately flooded with a highly concentrated solution of silver. The cauterisation was fortunately superficial, and the patient eventually made a good recovery. In a third case, the facts of which I communicated to the Ophthalmological Society in 1900, a lad, *æt.* 9, had been operated on for trachoma elsewhere by removal of the granulations by silver nitrate followed by irrigation of the eye with a solution of sodium chloride. When I saw the patient about a month later, I found extensive cicatrices of the conjunctiva and slight symblepharon, while in addition about two-thirds of one cornea was occupied by a greyish-yellow deposit, apparently of silver chloride. Vision was reduced to one-thirtieth of the normal. Lastly, I have notes of a case where a nurse rubbed the palpebral conjunctiva of a boy, *æt.* 11, with solid silver nitrate in mistake for some other application which had been prescribed. The results were serious, since one cornea became sloughy and eventually leucomatous, with sight equal only to the counting of fingers at half a metre from the face. Moreover, an adhesion formed between the inner part of the lower lid and the eyeball.

During recent years, a host of remedies, nearly all the output of the unceasing labours of the busy synthetic chemist, have been introduced as substitutes for silver nitrate. The list, already a long one, includes argyrol, protargol, largin, collargol, itrol, arginine, argentamine, and silver lactate. For most of these products it is claimed that, whilst as efficacious as the nitrate, they penetrate more deeply, possess higher bactericidal powers, do not stain the conjunctiva or the cornea, can be employed by inexperienced hands without risk, and, last but not least, that they cause little, if any, pain. Clinical investigation has confirmed some of these claims, and has at the same time negatived others. Certain of the agents named have already sunk into a deserved oblivion, but others appear calculated to replace silver nitrate in some, if not in all, of its applications at no very distant date.

For my own part, since I became thoroughly familiar with the action and uses of protargol, and more especially of argyrol, I have not employed silver nitrate in

the treatment of a single disease of the eye. Cases that once would have seemed to me to cry aloud for lunar caustic have yielded to the action of the newer remedies, so that what was once more or less of an experiment in my practice has been converted into a firmly established and very substantial fact.

In my subsequent remarks I shall consider briefly the advantages and disadvantages of the three silver substitutes of which I have had the most experience, namely, (I) Largin, (II) Protargol, and (III) Argyrol.

#### I.—LARGIN.

Largin, a synthetic compound, has not attracted so much attention from ophthalmic surgeons as, in my opinion, its intrinsic merits deserve. It contains 11 to 10 per cent. of silver combined with protalbin, and occurs in the form of a stone-coloured, granular powder soluble in water. It is a non-irritating bactericide possessing some astringent properties. I have employed largin as a 3 per cent. to 10 per cent. solution extensively in the treatment of superficial eye disorders more especially in the various forms of ophthalmia. Its application causes neither pain nor irritation in these strengths, neither is it followed by appreciable reaction. It has been claimed by Falta (*Centr. bl. f. prakt. Augen.*, February, 1899) that largin does not stain the conjunctiva after long-continued application, but my experience has furnished me with more than one instance where this complication was observed. Indeed, elsewhere (*Brit. Med. Journ.*, March 17th, 1900) I have published ten cases where argyrosis was produced by largin, and since then I have met with many more. Rightly or wrongly, I have formed the opinion that largin is more apt to stain the tissues than even silver nitrate itself.

In the gonococcal ophthalmia of newly-born children I have found that a 10 per cent. solution of largin is inferior to both silver nitrate and to protargol. The case is, however, altogether different as regards acute contagious ophthalmia, an affection common at certain seasons in England, and nearly always due to the tiny Koch-Weeks' bacillus. In twenty such cases, some of a severe character, a rapid cure followed the daily application to the conjunctiva of a 10 per cent. solution of largin. In acute trachoma, also, the same remedy yielded good results in subduing the obvious signs of inflammation, and in paving the way, as it were, for the use of more powerful means, escharotic or surgical. In blepharo-conjunctivitis, common in poorly-nourished and ill-cared-for children, and generally associated with pyococci (*s.p.* aureus and albus), a 3 per cent. solution gave good and speedy results when applied to the eyes three or four times a day. In suppurative affections of the lachrymal sac a similar solution, applied either as "drops" or by injection, succeeds admirably.

In brief, the application of largin is painless, but when prolonged beyond a few weeks, is apt to stain the conjunctiva of an indelible light-brownish hue. The more resistant cornea withstands the action of largin for longer than the conjunctiva, but eventually it also takes on the stain. Largin is an efficient substitute for silver nitrate in any of the conjunctival inflammations associated with the Koch-Weeks' bacillus, such as acute contagious ophthalmia and acute or subacute trachoma. Largin, in fact, is specific as regards that particular micro-organism, just as protargol is specific as regards the gonococcus. Largin also acts well in blepharconjunctivitis and in dacryocystitis. As is the case with all silver preparations, it is a matter of practical importance that largin should be brought thoroughly into contact with all parts of the diseased membrane.

#### II.—PROTARGOL.

Protargol can scarcely be mentioned without associating the product with the name of Dr. A. Darier, of Paris, to whom we owe the introduction into ophthalmology of this valuable synthetic product (*La Clin. Ophthal.*, January 10th, 1898). It is a combination of silver (8.35 per cent.) and protein, and is met with in the form of a yellowish powder, readily soluble in cold water.

My experiences with protargol have, upon the whole

been favourable as regards eczematous blepharitis (blepharitis ulcerosa), gonococcal ophthalmia, acute contagious ophthalmia, and suppurative affections of the lachrymal passages. Attention to the strength of the preparation I have found to be important. Thus, in cases of ophthalmia neonatorum, due to the gonococcus, 5 per cent. to 10 per cent. solutions, which I used at first, did not yield me any striking successes. They were, indeed, inferior to the 2 per cent. silver nitrate in common use. A 50 per cent. solution, to which I then resorted, gave results that it would be difficult or impossible to surpass. In acute contagious ophthalmia I employed a 10 per cent. to 20 per cent. solution with happy results, and in lachrymal affections a 3 per cent. to 5 per cent. solution. In many cases of blepharitis, cure was brought about by the thorough rubbing into the diseased part of an ointment containing 10 per cent. of protargol. But since I acquainted myself with Dr. Darier's soaping (*savonnage*) I seldom find it necessary to resort to the ointment. A 50 per cent. solution is used, and this is rubbed into the edges of the eyelids by means of a brush steeped in the liquid. A kind of *savonnage* of the parts is thus obtained, which is often capable of curing even rebellious cases of that unsightly disease.

To my mind, the disadvantages of protargol are two in number, and the recognition of these has prevented me from using the remedy as much as I formerly did. They are: (a) staining of the conjunctiva; and (b) pain and discomfort. The discoloration after prolonged use of protargol even exceeds that observed after the use of largin. After three months' employment once a day of a 10 per cent. solution I have seen the parts assume a dirty brownish hue as unpleasant to the patient as it was unsightly to the bystanders. Discomfort short of actual pain is a not uncommon complaint in my experience, but real pain, on the other hand, is distinctly rare. In some instances these drawbacks appear to be due to incorrect dispensing of the solution, to the keeping of stock solutions, or to the reducing effect of light. The water must be cold, and the powder must be dusted on the surface of the liquid, which is then allowed to stand until solution has taken place. On no account must hot water be employed. Small quantities should be made at a time, and the solution should be kept in non-actinic bottles.

### III.—ARGYROL.

We now come to a product, the latest and, in my opinion, the best of them all, which has popularised itself in a wonderful way since its introduction into practical ophthalmology less than three years ago (*Med. Record*, May 24th, 1902). It is known as argyrol, or silver vitellin. It contains no less than 30 per cent. of metallic silver combined with a proteid substance. Notwithstanding its high ratio of silver-content, I have never known it cause the least pain, irritation, or reaction. It is extremely soluble in water.

During the last eighteen months I have employed argyrol upon an extensive scale, chiefly in all kinds of conjunctivitis, in blepharitis, in phlyctenular affections of the cornea and conjunctiva, and in affections of the lachrymal passages. My experiments have been made with a 15 per cent. solution, and only in cases of gonococcal ophthalmia have I resorted to a 20 per cent. strength. The weaker liquid has been dropped into the eye three to eight times a day according to the kind and severity of the inflammation. The stronger liquid has been painted over the exposed conjunctiva once or twice in the twenty-four hours. An argyrol ointment, as will be explained later, has been used, chiefly in phlyctenular affections of the eye.

Almost the first thing that struck me about argyrol was the fact that many patients volunteered the statement that even after the initial application relief to symptoms was obtained. It thus appeared to act as a direct sedative to the inflamed mucous membrane. No single patient has ever complained of any pain attending its use. No caustic or escharotic action ever follows its use. To judge from its effect on cases of acute contagious ophthalmia, its powers of penetration must be of a very searching description. The sym-

ptoms of a sharp attack of acute conjunctivitis, due to the Koch-Weeks' bacillus, may be subdued in the course of two or three days, and that, be it remembered, without the least discomfort to the patient. I have further found argyrol capable of quickly healing those small peripheral ulcers of the cornea which are now and then associated with acute catarrhal ophthalmia in middle-aged and elderly people. As is well known, these small ulcers may become extremely painful, a symptom that speedily yields to argyrol. A 15 per cent. solution used as an injection in suppurative lachrymal affections has, in my hands, often dried up the muco-purulent secretion and materially assisted in restoring the tear passages to a healthy condition. In ophthalmia neonatorum, due to gonococcal infection, the 25 per cent. solution painted once or twice a day over the conjunctiva, exposed for that purpose by eversion of the lids and carefully dried from adherent discharge, with the frequent use by instillation of the 15 per cent. or of a weaker solution, will cure the case as quickly and certainly as any remedy with which I am acquainted. If ulcers of the cornea are present when the case falls under notice, argyrol is more than ever indicated, and should then be used twice a day. In such cases I believe I have seen benefit from letting the argyrol run freely over the ulcerated surface of the cornea, a thing that may be done with perfect safety.

Many cases of obstinate ulcerative blepharitis may be cured by rubbing the inflamed lids vigorously with a pledget of wool soaked in the 15 per cent. solution, and repeating the process, at first daily, and later at longer intervals. This, combined in the more severe cases with occasional cauterisation of the little ulcers lying at the roots of lashes with the acidum carbolicum liquifacuum of the "British Pharmacopœia," is the best treatment that I have ever adopted in long-standing and rebellious cases. It need scarcely be added that before the argyrol is used every trace of scab should be removed from the inflamed edges of the eyelids. An ointment containing 10 grains of argyrol to the ounce of vaseline acts well in many cases of eczematous (phlyctenular) conjunctivitis and keratitis, and if marked photophobia and blepharospasm be present, two to four grains of alkaloidal atropine may with advantage be added to the prescription. The ointment, simple or combined, should be applied two or three times a day. There are few cases even of the most intense blepharospasm that will not yield to this treatment, especially if at the same time the patient's forehead be painted daily with liniment of iodine until the skin becomes sore and slightly cracked. I need say nothing of constitutional remedies, which are called for in practically every case.

The only form of conjunctivitis in the treatment of which argyrol has disappointed me is in the chronic or subacute form due to the Morax-Axenfeld diplobacillus, the so-called "angular blepharitis," where the zinc salts, in rather strong solution, have seemed to me much superior.

It has been claimed that argyrol never stains the conjunctiva, no matter in what concentration or for how long it may be applied. If this be true, it at once gives argyrol a superiority over the other salts of silver, organic or inorganic. The claim, however, needs some slight modification, inasmuch as in one case I have seen argyrol produce slight argyrosis. The facts are as follows:—Miss E., æt. 54, suffering from a chronic and rather severe palpebral conjunctivitis, was ordered a 15 per cent. solution of argyrol for use four times a day on August 22nd, 1903. On October 2nd, the number of applications was increased to five a day. On January 13th, 1904—that is to say, after she had used the remedy for 144 days—a very faint staining of the palpebral conjunctiva was noted. This is the sole instance I have met with.

### CONCLUSION.

Silver nitrate, although invaluable in the hands of those who know how to use the remedy, is apt to become a somewhat dangerous weapon if employed without due experience, skill, and discrimination. The knowledge of this fact has led chemists to endeavour

to find an agent that shall possess the antiseptic powers of silver nitrate without its undesirable qualities. It has been recognised that the clinical value of a silver compound depends upon the amount of the contained silver, and that is modified, often in an undesirable direction, by the other chemical constituents of the salt (see *Ophthalmoscope*, March, 1904). Hence, the last few years have witnessed the production of many new silver compounds belonging to the organic class. The ideal agent, according to Fraenkel, must fulfil the several requirements of not coagulating albumen or of precipitating sodium chloride, of ready solubility in water, of not producing pain or of setting up irritation when applied to the eye. Largin, protargol, and argyrol fall more or less in line with these requirements. The staining propensities of largin and especially of protargol make me give the preference to argyrol as an agent for general employment. So far as my personal experience goes, it never does the least harm, while it is, without doubt, an efficient, speedy, and painless remedy in most superficial affections of the eye.

## THE PERSONAL ELEMENT IN THE ADMINISTRATION OF ANÆSTHETICS. (a)

By V. G. L. FIELDEN, M.B., B.Ch. R.U.I.,  
Senior Anæsthetist, Royal Victoria Hospital; Anæsthetist, Belfast  
Ophthalmic Hospital, and Ulster Hospital for Women and  
Children, &c.

THE title of this paper may be a little ambiguous, so, at the outset, I must mention that I do not mean by "personal element" that of the anæsthetist, but entirely that of the patient.

No two persons are exactly alike, and so the anæsthetist finds that his patients do not correspond in every detail. It is in consideration of some of these personal points which I have met with in my work that I desire to occupy your attention for a brief space.

I am frequently asked by students: "How do you know when a patient has had enough?" I briefly recapitulate the different stages of anæsthesia with their signs, and these embryo practitioners probably go off quite satisfied in their own minds that they will be able to give anæsthetics as soon as they have gained the coveted degree or diploma. These students are not asked by their examining bodies to produce a certificate of having devoted a certain amount of time to this branch of their profession, so they do not consider it worth while to voluntarily attend a short course of lectures and demonstrations on such an important subject. A small percentage of students in a medical school will be found to be interested in the subject for its own sake, but the majority, knowing that there will be not even a single question on the subject, will become qualified to practise without having considered the rudiments of anæsthetics and their administration. Their qualifications to practise, however, entitle them to administer such potent drugs as anæsthetics, and the general public consider their freshly acquired degree or diploma a guarantee of their ability "to give chloroform."

Many practitioners remain content with a knowledge of the general signs of anæsthesia without a thought of any peculiarity, from disease or otherwise (the personal element), on the part of the patient. "He took the anæsthetic very well" and "he took it very badly" are common expres-

sions. The latter may be due to faulty administration or to the personal element on the part of the patient, in whom some condition, known or unknown, renders a perfectly smooth condition of anæsthesia more or less impossible, and it is only experience or alert thoughtfulness which can forestall or control difficulties as they arise.

Numbers of such cases are to be met with, and Hewitt has given us the benefit of some of his valuable observations in two lectures entitled "The Anæsthetisation of So-called Bad Subjects" (*Lancet*, January 10th, 1903). In these he points out the part played by such familiar conditions as nasal or other obstructions liable to cause respiratory embarrassment; a full set of powerful teeth set in a strong jaw; a very muscular man, and a man of the "John Bull" type, &c. A full and careful perusal of these lectures by such an authority will amply repay the reader.

*Alcoholism.*—This is perhaps the most familiar of examples of the patients' personal element so far as it affects the production and maintenance of anæsthesia. Alcoholics are admittedly bad subjects, and we approach them with a certain amount of dread when the administration of an anæsthetic is desired. It is not an absolute necessity that alcoholism is synonymous with difficulty. Occasionally it will be found an easy task to anæsthesise an alcoholic. I have given an anæsthetic the day after a "spree" without the slightest trouble. On the other hand, a dentist and I had quite a little scrimmage with a young fellow before anæsthesia resulted. He admitted having had five glasses of brandy during the day, and it was then only 3 o'clock.

I have come to consider that the ethyl chloride-ether sequence is the best for inducing anæsthesia in an alcoholic.

*Fear.*—This is a great source of worry and trouble to an anæsthetist, and it has been the cause of many so-called accidents. I have had many very nervous patients to deal with, whom it was difficult or impossible to reassure. I have heard them give directions regarding the care of their children and their affairs, fearing approaching death, even after being seated in a dentist's chair or placed upon the operating table. Such cases would be enough to scare a timid administrator, and cannot fail to increase the anxiety of an experienced anæsthetist. Should a fatality occur the anæsthetic or the anæsthetist would no doubt be accredited with the death, whereas fright has no doubt had more to do with it. That death from fright can occur has been proved. One case occurred in Edinburgh. The patient was placed on the table, and before the administration was commenced was found to be dead. Hewitt quotes a case of Kappeler's, and two cases of death from fear prior to the administration of an anæsthetic are the subject of a leading article in the *British Medical Journal*, February 21st, 1903. Had even the smallest quantity of anæsthetic been inhaled in these cases they would have been branded deaths due to the drug. There is no doubt that the element of fear is one to be dreaded by any administrator. May I mention that it is decidedly wrong for an operator, in attempting to reassure the patient and friends, to make the dogmatic statement that there is absolutely no danger, for it would put the anæsthetist in a most unfortunate position should a fatality result?

(a) Paper read at a meeting of the Belfast Division of the Ulster Branch of the British Medical Association.

**Shock**, either due to the condition requiring operation or occurring during operation, is a source of increased danger and requires the exercise of such care. I have met with it prior to operation in cases of severe accident with or without the loss of blood, in cases of rupture of the bowel or stomach, &c., and during operations in abdominal surgery, where a profound impression has been made on the solar plexus and acting reflexly through the vagus. Once did I meet it in enucleation of the eyeball following pan-ophthalmitis. Stretching of the sphincter and cutting the cord in excision of the testis are liable to cause shock. In his Address on Surgery at the recent Oxford meeting, Sir Wm. MacEwen dealt at length with the cardiac and respiratory reflexes which may be obtained through the pudic nerves, and I am glad to see that he does not now blame the anaesthetist as he once did. In such conditions, where shock is either present or its occurrence feared, a preliminary injection of strychnine ( $\frac{1}{16}$  gr. for an adult) and either ether or a mixture containing it is, in my experience, the best method of procedure.

**Glycosuria** is a condition in which one fears ill after-effects. I have had a few such cases, and I always give ether if at all possible, and my reason is, that chloroform has been known to be followed by sugar in urine which had hitherto been free. I have had invariable success with ether and no ill after-effects. Coma has followed the administration of an anaesthetic in diabetes. I have not seen it. One case that I have notes of had slight glycosuria when admitted to hospital. This had disappeared by dieting before operation for a radical cure of hernia. I gave ether for an hour, and no sugar appeared as a result.

**Albuminuria** is another condition which induces me to give ether unless otherwise contra-indicated. Thompson, Buxton, and Levy have demonstrated that there is "no specific ether effect" upon the kidney. Chloroform, on the other hand, has occasionally caused albuminuria.

**Pregnancy**.—Apart from anaesthetics given in obstetric practice I have been called on frequently for surgical or dental cases during pregnancy, and my experience goes to prove that it is not a contra-indication to the use of an anaesthetic. Perhaps my best example was a case of nephrectomy taking over an hour during the fourth month. The patient returned to hospital and was delivered at full term.

**Empyema** cases are particularly anxious ones, especially as the majority are operated upon by turning the patient upon his sound side for the benefit of the surgeon.

**Coma**.—Only once have I had to give a comatose patient (a girl,  $\text{aet. } 17$ ) an anaesthetic (trephining for cerebral abscess). There was no conjunctival and slight corneal reflex when the patient was placed upon the table. I gave A.C.E., and very little of that was necessary.

**Valvular Disease** is not a contra-indication to the use of an anaesthetic if compensation is perfect. Care is very necessary that no undue strain is put upon the heart in any way. I have had two cases with double aortic murmur and used ether. Mitral disease is much more common. Irregularity is a greater cause for anxiety. In one case in which I gave ether for the amputation of a foot in a young man, the heart became irregular during the administration and remained so the following day. It was, no doubt, functional.

Certain conditions arise during the administration which must influence more or less the administrator.

**Vomiting** is a very familiar cause of trouble on the part of the patient, especially to the inexperienced, the reason being that he is not able to keep up such an even degree of anaesthesia as one with more practice. Some patients do not suffer from nausea or vomiting to even the slightest degree, whilst others are greatly upset by it. When a patient vomits during an operation it is a sign that he is not getting enough—in other words he has returned to the second stage of anaesthesia in which the vomiting centre is no longer paralysed. It is the more frequent inability of the inexperienced to maintain evenly the third stage that accounts for his greater trouble with this troublesome complication. The older teaching that alteration in the size of the pupil is an index of the onset of vomiting is fallacious. I have several times seen the pupil remain contracted during vomiting. Swallowing movements and pallor are frequent precursors. Vomiting is mostly due to the irritation of the vomiting centre by the anaesthetic, and its irritability varies greatly in different individuals. The swallowing of saliva in which some of the anaesthetic is dissolved no doubt is a cause of vomiting by its action upon the mucous lining of the stomach. I have had frequent opportunity of proving the fact that a patient who suffers from prolonged and severe vomiting after chloroform may suffer little, if at all, after ether given for a further operation.

Vomiting after ether, though more frequent than after chloroform, is usually not so severe, but I have notes of one remarkable case in which it persisted from Wednesday morning till Saturday evening after ether given for an appendicectomy.

**Faecal vomiting**, or, as I think it should be more properly called, faecal regurgitation, as a symptom of the condition requiring operation should be accepted as a warning for great care. The fluid regurgitates from a stomach more or less distended, the only means of exit (for example in intestinal obstruction) being by the mouth, and the epiglottis is not closed as in the act of true vomiting. Respiration proceeds normally and the inspiratory act draws the faecal fluid into the trachea. I have once seen death result in this way, and I determined that in all such cases I would wash out the stomach prior to giving an anaesthetic. I have more fully reported this and a successful case elsewhere (*MEDICAL PRESS AND CIRCULAR*, January 27th, 1904), and since I have added half a dozen more cases to my list in which I have drawn off the faecal fluid by a syphon tube, and then washed out the stomach. In this way I considerably reduced the danger and difficulty in what are acknowledged to be bad subjects for anaesthetics.

**Spasm**.—This may be general, as is more particularly seen in very muscular individuals, or it may be local—*e.g.*, of the jaw or of the glottis. Heavy smokers are liable to spasm of the jaw, and Hewitt suggests that it may be due to hypertrophy of the muscles caused by constant puffing or pulling of the pipe, &c. Spasm of the glottis may be the effect of an unusual delicacy of the mucous lining, or it may be that too concentrated a vapour is being inhaled. In either case a more dilute vapour must be used. Impure drugs which may be the source of trouble must of necessity be avoided. Spasm of the jaw is much more common than that

of the glottis and may be very severe. The worst case I have had was in a tetanus case with some trismus, to whom I administered ethyl chloride for the amputation of a toe. Forcible use of the gag sufficed to remedy the condition.

*Cyanosis* may be the result of spasm of the jaw or larynx, or it may occur independently of either. Its presence must always make an anæsthetist very watchful, for whatever the cause there is great risk of unhappy cardiac effects. Forcible opening of the mouth and traction upon the tongue may relieve the cyanosis, and sometimes the gag, with or without pushing forward the angle of the jaw, may suffice. In desperate cases tracheotomy may be the only remedy. I have not had to resort to the use of the tubes which I always carry in my bag. I recently had a case in which deep cyanosis resulted when the patient was placed in the Trendelenberg position. Both gag and tongue forceps failed to relieve it in the slightest degree, and it was only when the flat posture was resorted to that it passed off. Another bad case that I have notes of was that of a gentleman who was to have hæmorrhoids removed. Chloroform caused deep cyanosis, whilst ether added to the trouble by causing such a great amount of coughing as to interfere with the operator who, learning the state of affairs, worked against time whilst I proceeded cautiously for a very uncomfortable twenty minutes. This patient smoked cigarettes to such an extent that he had furnished himself with a pound box of them for consumption during his stay in the private hospital. I have notes of two cases (twin girls, æt. 12) who both coughed severely and became cyanotic whilst getting chloroform prior to the removal of adenoids. Was its occurrence in both merely a coincidence or was it a natural tendency or due to the adenoids? I am not able to say which.

Several of my cases have demonstrated the fact that cyanosis may result from the presence of food in the stomach. In such cases it passed off when the stomach emptied itself by vomiting.

I have several times noticed the great tendency to cyanosis that there is in patients in the Trendelenberg position, who retch unless very deeply anæsthetised. The profound anæsthesia necessary to avoid annoyance to the surgeon, together with the effect of gravity, may be a source of great anxiety to the anæsthetist.

Milder respiratory effects than the foregoing are more frequent, e.g. :—

*Cough and Holding the Breath*, both of which are more common with ether or a mixture containing ether. Cough is generally the result of the direct effect of the anæsthetic on the respiratory mucous membrane, and in patients who are very irritable it may occur during deep anæsthesia. Should ether be the anæsthetic used it may be necessary to change to chloroform, and if it occurs with the latter the administrator will require to exercise his best endeavours to keep the patient anæsthetised with as dilute a vapour as possible. I have notes of one case in which there was frequent cough under chloroform, which was greatly diminished by painting the nasal cavities with a solution of cocaine. Cough may be due to excessive bronchial secretion. Even under chloroform I have seen such profuse secretion that cyanosis and cough both occurred, and it was necessary to encourage the coughing at intervals. Such cases fortunately are rare.

*Holding the Breath* may be due to too concentrated

a vapour, but, apart from this, is common in very nervous patients. When it occurs it is well, especially if chloroform is being given, to allow a free breath of air, as great risk is incurred by the inhalation of chloroform-laden vapour with the very deep breath which naturally follows.

*Excessive Buccal Secretion* requires removal either by occasional sponging or by a simple device suggested by Blumfeld (a) in his little book—viz. by the corner of a towel tucked into the dependent cheek, which has a syphonage action. I have found this hint very useful.

*Hiccough* is occasional. I have seen it a few times, but never very severe.

*Sneezing*.—This occurred several times in a young fellow during the inhalation of chloroform for enucleation of the eyeball for syphilitic iritis.

*Epilepsy*.—A history of this tends to increase our anxiety lest a fit should be induced.

I have had four or five cases, but in none did any trouble occur—one of the cases had had a fit in the external whilst being examined a few days previously. I have, however, notes of one case, without an epileptic history, which resembled what is described as an epileptiform seizure.

*Dilated Pupils* persisting after abolition of the corneal reflex puts an anæsthetist upon his mettle. This symptom may (but not invariably) be found under the following conditions :—

1. Digestive disturbance.
2. Shock, either before or during operation.
3. With profuse hæmorrhage.
4. After struggling.
5. In presence of the following three conditions—*anæmia, emaciation and pyrexia.*
6. After the general or local use of atropine or belladonna.
7. In those who have been very frightened.
8. With cyanosis.

I could quote many cases I have come across, but time does not permit. The greatest care is necessary in such cases lest, in trying to obtain contraction of the pupils, the anæsthetic is pushed too far.

*Unequal Pupils*.—I have frequently been able to demonstrate to students and others the presence of this condition. One pupil may be well contracted, whilst the other may be more or less dilated. This always increases my anxiety, for when present after abolition of the corneal reflex one cannot help feeling that the dilatation of one pupil may be a sign of danger. I should be glad to learn the significance of this phenomenon. I have thought that it may be due to some difference of refraction, but can offer no proof of this theory. Whilst writing this paper I had an exceedingly good example of it in the Royal Victoria Hospital. Dr. MacIlwaine and Dr. Nelson very kindly examined the eyes for me, but found such a very minute difference in the refraction of the two eyes that it hardly supports my theory.

I do not profess to have dealt with every condition on the part of the patient which must weigh with us in the administration of an anæsthetic, nor to have gone into detail in those on which I have touched; much more time would be necessary than is available at this meeting. I trust, however, that what I have said is sufficient to show that the proper performance of this branch of our profession is not such a sinecure as too many seem to suppose.

### Clinical Records.

#### FALLOPIAN TUBES, LIGATURED TWICE AT PREVIOUS OPERATIONS, AND REMOVED IN THE CASE OF A THIRD CÆSAREAN SECTION. (a)

By J. W. TAYLOR, M.D., F.R.C.S.,

President of the British Gynæcological Society; Professor of Gynæcology in the University of Birmingham.

THE history of these specimens is as follows:—M.S., a strumous dwarf, æt. 25, with both curvature of spine and contracted pelvis, was married in July, 1900. She immediately became pregnant, and was sent to me for operation by Dr. Darroll, of Leintwardine, in February, 1901.

Labour commenced on the morning of March 20th, when I operated by Cæsarean section, removing a healthy female child which is still living. After suturing the uterine wound, I tied each Fallopian tube by a single ligature of silk as some bar to further pregnancy. The mother and child both did well, and left the hospital on April 17th, but remained at our Convalescent Home for some time longer. The following year (1902) the patient developed tuberculous disease of the right knee-joint, and her leg was amputated above the knee at Shrewsbury Infirmary on September 22nd, 1902. In 1903 she again became pregnant, and was sent up to me once more by Dr. Darroll towards the end of August. I did a second Cæsarean section on September 14th, 1903, removing again a living female child, which, however, was very feeble, and only lived about half an hour. After the suturing of the uterine incision was completed, I carefully examined the Fallopian tubes, and found considerable atrophy at each site of ligature. The atrophy was most marked on the right side, where the tube seemed narrowed to a point. The silk had been absorbed. I placed two fresh ligatures of silk on each Fallopian tube (four ligatures in all, but without any cutting or removal), and closed the abdominal wound. The patient did well after the operation so far as the section was concerned, but during the whole of the time of her stay in hospital she was troubled with chronic strumous conjunctivitis and ulceration of the cornea, an affection from which she had been suffering for nearly two years, in spite of the free administration of cod-liver oil. She went to the Convalescent Home on October 8th, 1903.

Early in this year I heard from Dr. Darroll that from the date of her return home she had never menstruated, and was evidently again pregnant. She came up in July last, and I found that this was indeed the case. On this occasion I determined to remove the uterine appendages, but was anxious not to hurry the performance of the operation so as to obtain a living child, if possible.

On August 4th I went for a holiday, and two days later, the patient beginning to be in labour, my colleague, Mr. Christopher Martin, kindly operated for me, removing a living child, which, like the preceding one, only lived about three-quarters of an hour.

Mr. Martin, before closing the abdomen, removed the whole of each tube, and a small portion of each corresponding cornu of the uterus. He also removed one ovary. The patient made a good recovery, and left the hospital soon after my return on September 7th.

On looking at the tubes removed, it may be seen that one tube is as completely divided by the double ligature as if a piece had been cut out of it, while in the other the whole of the muscular coat appears to be gone, but (in all probability) the mucous channel is still pervious.

In addition to the direct interest of these specimens as contributing to the general sum of knowledge regarding Cæsarean section, and the utility or non-utility of ligature of the tubes as a bar to future pregnancy, I must confess that they have a very

considerable interest to me as bearing on the question of the causation of tubal pregnancy.

It would, I suppose, be difficult to find two Fallopian tubes in which an ovum would be theoretically more likely to be stopped on its journey to the uterus, yet the pregnancy on each occasion after ligature was uterine and not tubal.

It seems to suggest that the cilia of the epithelial coat, even within the lumen of the tube, have more to do with the progress of the ovum than any peristaltic muscular contraction.

#### A LARGE ABSCESS OF THE OVARY.

THIS specimen is, I believe, a rather rare one, it being unusual to find so large an abdominal tumour due to ovarian abscess. The history is interesting:—The patient, Mrs. C. C., had been married five years, but had never been pregnant, when in August of this year she developed a rising temperature with obscure abdominal pains, and, rather naturally, was supposed to be suffering from typhoid fever.

She was seen on August 21st by another consultant, who diagnosed suppuration, and opened an abscess by the vagina on the 23rd, over a pint of pus and blood being evacuated.

This undoubtedly gave her very great relief, and she was able to get up and go out of doors a little later; but since this date an increasing enlargement was noticed in the lower part of the abdomen, the catamenia having ceased from the date of her illness.

When she was sent to me by Dr. Kingsland, about the middle of November, I found a remarkably prominent cystic swelling reaching to the umbilicus, and looking like a five months' pregnancy or a very distended bladder.

On examination, however, I found it was due to neither of these conditions, but to a tumour of the left ovary or left broad ligament pushing the uterus to the right. The lower pole of the cyst came down to the level of the vaginal cervix on the left side, the side of the uterus being apparently fixed to the wall of the cyst, and a diagnosis was made of adherent ovarian tumour or broad ligament cyst. The patient's temperature was never quite normal, but usually slightly raised; on the evening of admission into hospital it was 101° F. Under anaesthesia, on November 19th, I came to the conclusion that the tumour must be intra-peritoneal, and operated by abdominal section, removing a large single abscess of the left ovary, with dense adhesions to the pouch of Douglas at the site of the first tapping, or incision. As there was necessarily some fouling of the pelvis in the separation of these adhesions, I finished the operation by posterior vaginal celiotomy and gauze drainage. The pus removed was examined by my assistant, Dr. Smallwood Savage, and showed a pure growth of bacillus coli, but at no time during the operation was there any visible adhesion or channel of communication found between the ovary and the rectum. The patient made a good recovery, and went to the Convalescent Home two days ago.

### Transactions of Societies.

#### BRITISH GYNÆCOLOGICAL SOCIETY.

MEETING HELD THURSDAY, DECEMBER 8TH, 1904.

PROFESSOR JOHN W. TAYLOR, M.D., F.R.C.S.,  
President, in the Chair.

#### SPECIMENS.

##### CARCINOMA OF THE FALLOPIAN TUBE.

DR. MACNAUGHTON-JONES said that he exhibited this specimen solely for its pathological interest. For some years he had lost sight of the case from which the tumour was removed, and it was only recently that he had discovered the latter among others in his collection. When he had sent it for examination and report to Dr. Cuthbert Lockyer, it proved to be one of exceptional interest. The report was as follows:—"The tumour is oval in shape,

(a) Read and specimen shown at the British Gynæcological Society, December 8th, 1904.

and measures 10 inches in its greatest and 8 inches in its shortest circumference. It has a lobulated surface; some of the lobes are smooth, the growth being enclosed in a highly-stretched fibrous-looking shiny capsule. Other lobes are rough and papilliform, consisting of growth which has burst through the containing capsule. The smooth thin capsule has been peeled off the greater part of one portion of the growth, revealing a rough surface studded with nodules the size of a pin's head. A further portion of the tumour has been cut through its greatest diameter, the cut surface has a pale yellow colour, and consists of soft friable granular-looking material. At one point there was a small projection which admitted a fine bristle. This on transverse section proved to be the cut end of the Fallopian tube. On following this up it was found to lead through the capsule into the cavity containing the new growth. Sections have been prepared at various levels to show that the capsule of the growth is continuous with the wall of the undilated tube. These sections prove that the smooth capsule enclosing the tumour consists of fibro-muscular tissue continuous with that forming the wall of the unexpanded tube. The tumour is, in fact, of tubal origin."

Dr. Macnaughton-Jones remarked that unfortunately the clinical history of the case had been lost sight of, and he could not say what the ultimate issue was. In Mr. Alban Doran's recent paper in the *Journal of Obstetrics and Gynaecology*, October, 1904, there was a table of over fifty complete cases of primary cancer of the Fallopian tubes. Graefe, of Halle, had in 1902 found fifty-two recorded cases.

Mr. BOWREMAN JESSETT said that he had never met with a case of primary columnar-celled carcinoma of the Fallopian tube, and suggested that the specimen might possibly be a secondary growth of carcinoma of the bowel.

Dr. F. A. PURCELL also spoke of the extreme rarity of primary carcinoma of the tube, and suggested that there might have been primary growth in the uterus.

Dr. C. F. H. ROUTH asked what was the age of the patient.

Dr. MACNAUGHTON-JONES, in reply, said that the capsule of the tumour was a direct extension of the Fallopian tube; the analysis of Mr. Doran's cases showed that the uterus was involved in only six out of 53 instances.

The PRESIDENT showed "Fallopian Tubes Ligatured Twice at Previous Operations, and removed in the course of a Third Cæsarean Section"; also a specimen of a "Large Abscess of the Ovary." Notes of these cases will be found under the heading of "Clinical Records," page 657.

The PRESIDENT also exhibited three cases of CANCER OF THE BODY OF THE UTERUS, reading notes as follows:—The first, a simple case of cancer of the body, occurring in a married woman of 56 years of age, four years after the menopause, attended by the classical symptoms of watery, foul-smelling and bloody discharges for three months before operation. The uterus was removed by vaginal hysterectomy on October 31st, and on being laid open disclosed a fairly typical and very pretty specimen of the disease. The patient made a good recovery.

The second case appeared, clinically, to be one of ovarian tumour, complicated by a small uterine polypus or fibroid. The patient was single, æt. 43, never regular, the last normal period having taken place some three years previously; since then she stated that she had suffered from a daily coloured discharge, never profuse, and never amounting to more than a "show." On examination, she was found to have a large abdominal tumour reaching well above the umbilicus. The uterus was pushed backwards by the tumour; the cervix was open, and a small growth, like a polypus, which did not break down or bleed on examination, was just to be felt by the tip of the examining finger. I operated on November 17th, and on first attending to the condition of the uterus under anæsthesia

found that the growth presenting at the cervix was soft, brain-like, and almost certainly malignant. I therefore proceeded to remove the whole of the uterus as well as the ovarian tumour and the uterine appendages of the opposite side, hoping in this way to obtain freedom—or a longer freedom—from recurrence. The patient has done well, and is now convalescent. The uterine growth has been examined by Professor Leith, who reports upon it as malignant. The ovarian tumour is still under examination, but presents the rough general characters of malignancy.

The third case was originally one of myoma of the uterus, attended for several years by menorrhagia. The patient, a midwifery nurse, single, æt. 52, appeared to have passed through the menopause 18 months ago, and the hæmorrhage ceased. For six months an irregular foul-smelling discharge returned, and, in September and October last, she suffered from severe hæmorrhage with "floodings." The patient was virginal, and the vaginal cervix was free from any tangible ulceration. The tumour filled the pelvis, and therefore no estimate could be made of the fixation. The abdominal characters of the tumour were those of a fibroid. The diagnosis was made of cancer of the uterus or a "sloughing" fibroid, and I operated on December 1st, doing a pnhysterectomy by the combined method. There was pyometra and right pyosalpinx, and the extraction of the tumour was by no means an easy one. During its removal the uterus tore at the junction of the body with the cervix, and the latter, which was removed separately, was unfortunately not preserved. The pathological examination appears to show that a malignant adenoma is invading a myomatous uterus, but the case is too recent to obtain a full report. The patient (to-day) is doing well.

Dr. HEYWOOD SMITH said that ligature allowed a certain amount of patency in the lumen of the tube; more radical measures were required to ensure sterility.

Dr. J. A. MANSELL MOULLIN concurred as to the inadequacy of ligature; the easiest and best course to adopt is to remove the whole of the tube at the primary operation.

Dr. J. H. DAUBER remarked that cases had been recorded in which both ovaries had been removed and yet the patient had become pregnant.

Dr. J. FURNEAUX-JORDAN said that Cæsarean section was now attended with such good results that he did not see the necessity of sterilising a young woman merely because she could not have a child born through the pelvis.

Dr. MACNAUGHTON-JONES remarked that in some of these cases the method introduced by Pincus had been successfully employed to seal up the uterine canal by atmocausis. In regard to the specimen of carcinoma of the fundus, it was precisely similar to a case brought forward by him before the Society, and from the appearance of the uterus it did not seem that the cervix uteri was involved. In his case it was proved microscopically not to be so. It would be well that the specimen were examined to settle this point.

The PRESIDENT, in reply, said that though they now knew that ligaturing the Fallopian tube was a very poor bar to future conception, his critics must remember that in 1900, which was the date of his case, their knowledge was by no means so complete. However tightly a ligature was tied, the serous membrane and muscular tissue might offer such resistance that, in spite of the ligature, a minute aperture might be left through which the ovum could pass. The surest method of ensuring sterility was, he thought, that adopted by his colleague, Mr. Martin: to remove not merely the tube, but also the corresponding cornu of the uterus by a wedge-shaped or triangular incision, and to bring the edges of the wound together, so as to close the channel effectually by some depth of muscular tissue. For closing the wound in the uterus, he always used sterilised silk, and had not employed gut for that purpose for many years. The large ovarian tumour removed with the uterus, diagnosed

to be cancerous after curettage, had all the microscopic characters of a carcinomatous tumour, and if proved to be one, must have existed for several months before anything was known to be wrong with the uterus.

Dr. WILLIAM ALEXANDER read a paper on

ADENOMA OF THE ENDOMETRIUM,

illustrated by microscopical sections, photographs, and lantern slides, which will be found under the heading of "Original Communications," on page 649.

Dr. F. A. PURCELL noted that in some of the cases the ovaries had not been removed with the uterus. It was only of recent years that due consideration was being given to a conservation of the ovaries on account of the value of their internal secretion. He thought that the ovaries, if apparently normal, should never be removed.

Dr. MACNAUGHTON-JONES said that he had brought cases precisely similar to those described by Dr. Alexander before the Society, in which the adenomatous changes mentioned by him had been present. In the new edition of his book, the macroscopical and microscopical appearances mentioned by him were fully illustrated, and at the last meeting he had shown a uterus in which the cavity was filled with the same gelatinous and mucoid substances as described by Dr. Alexander. It was due to the breaking down of the epithelial *débris*, and the hæmorrhage was caused by necrosis of the vessels, the result of pressure due to the glandular change. The subject was a very important one, as the recurrence of the hæmorrhages brought about a most serious condition, and at times a profound anæmia. Curettage was useless as a means of treatment, and the proper course to pursue in these cases, when the diagnosis was made, was to remove the uterus. In certain of these cases the ovaries were also diseased, and if so, they should be removed with the uterus.

Mr. BOWREMAN JESSETT, alluding to the gelatinous condition of the uterine mucous membrane, said he had not the slightest doubt that it was a pre-cancerous condition, and that certainly in the first case, if left alone, it would have developed into malignant disease of the fundus of the uterus; he had seen several cases of the sort, but the diagnosis of such pre-cancerous conditions was still obscure. It was a question whether in a woman of forty years of age, suffering from persistent uterine hæmorrhage, one would be justified in removing the uterus, if microscopical examination of the scrapings by the curette did not show malignancy. He thought not in the majority of cases. But he was certain that he had seen cases pronounced to be non-malignant on such examination afterwards prove to be so. If these pre-cancerous conditions could be detected earlier, and the uterus removed in time, many a woman's life would be saved.

Dr. J. A. MANSELL MOULLIN said that though the curette in these cases was not an efficient cure, it was still of great value in diagnosis, as, when it did bring away malignant tissue, the removal of the uterus was clearly the only right course to adopt.

Mr. FURNEAUX-JORDAN stated that in the first five cases he had operated upon for this disease he had previously tried in vain to stop the hæmorrhage by the use of the curette, but in the last three cases he operated on had not done so, as he had come to the conclusion that it was not advisable. If profuse hæmorrhage, such as occurred in this disease, was allowed to continue, the patient would probably die before malignant disease had time to show itself. The condition was a most serious one, and required radical treatment.

Dr. ROUTH confessed that in the course of his practice, rather a long one, he had never had occasion to remove a non-cancerous uterus. He had not found scraping of the uterus of much use; much better results would follow the intra-uterine application of the strongest carbolic acid. In several cases of persistent bleeding, even with a bad odour, he had cauterised the uterus with a red-hot iron; this had

never caused any bad symptom, and the patients had got perfectly well. There was no justification for removing the uterus for hæmorrhage, unless it was certain that the case was one of malignant disease.

Dr. HEYWOOD SMITH thought that in case met with sufficiently early, intra-uterine measures should be tried. Chloride of zinc might destroy the hæmorrhagic condition, and give the uterus a chance to recover itself, nor did he see why the actual cautery should not be applied. Such an application might stop the hæmorrhage, but if not he would consider the advisability of removing the uterus.

The PRESIDENT, after cordially thanking Dr. Alexander for his paper, said that the question of glandular inflammation was certainly the one that at present was attracting most attention from gynæcologists, and the more it was studied the less possible it seemed to draw a definite line between that condition and cancer. There was much in what Dr. Routh had said regarding the treatment of the disease in its early stages. Mr. Lawson Tait employed the actual cautery extensively, and with good results, but it was questionable whether the condition of the patient after such treatment was better than after the removal of the uterus. He asked Dr. Alexander whether in adenoma of the endometrium he included all cases of metrorrhagia. He had himself met with cases in which microscopical examination disclosed a growth in the tubes after the removal of the uterus; in others fibroid thickening was all that appeared. The diagnosis was a matter of great difficulty, especially when one had to rely entirely on the symptoms of the patient and the hæmorrhage; he had known instances in which bleeding had been profuse and almost continuous for two or three years, in spite of repeated curettings, and without any assignable cause had diminished, and at the menopause ceased, and some years afterwards the patient had continued quite well.

Dr. ALEXANDER, in reply, said that he always left the ovaries behind, as he believed this made the convalescence more satisfactory. He did not think that the disease was malignant; at all events, in his experience it seldom became malignant. His first patient after eighteen years did not seem to have any more of the growth than she had at the beginning of that time. In another case the bleeding has been going on for twenty years; the patient is still alive waiting for the menopause, and probably not any worse now than she was many years ago. Hysterectomy should only be performed in these cases when all other means have been fairly tried and have failed. When this is the case, the treatment, nowadays, of removing a uterus that had become useless and only a source of weakness to the patient can hardly be called heroic. In these cases the operation is a very simple and safe one for a very grave disease. He always removed the uterus in these cases *per vaginam*, and did not think there was any reason why it should ever be removed through the abdomen. He thanked the President and Fellows for their very kind remarks on his paper.

ECTOPIC GESTATION,

Dr. R. T. SMITH showed a specimen and read the following notes:—The patient was a Polish Jewess, æt. 30, married two years, with a child one year old, and the facts elicited were simply that four weeks ago, after two months' amenorrhœa, she was seized with sudden pain in her left side, and from that time had had a sanguineous discharge with clots. Examination revealed a soft swelling in the left side of Douglas's pouch, an old retro-uterine hæmatoma. At the operation, the tumour forming the adventitious sac, so well shown in the specimen, was surrounded by a considerable amount of blood, the escape of which had probably caused the pain. The anterior wall of the tube was extremely thin, and evidently on the point of a second rupture. The patient made an uninterrupted recovery. The interest of the specimen lay not so much in any special pathological feature as in its

structural completeness; the tumour was entirely tubal, the foetus with the head towards the uterus filling the whole tube, and also in the fact that the diagnosis depended almost entirely on the physical examination, the patient knowing so little English as practically to be unable to give any account of her illness.

DR. BEDFORD FENWICK showed a specimen of UTERINE FIBROID WITH UNUSUAL DEGENERATION.

The patient was *æt.* 31. She had been married thirteen months, and was confined on August 4th, 1904, at full time. The periods began at fourteen, had always been regular, lasting six or seven days, always profuse, and with slight pain. Since the labour, she had had increasing losses, and for some time past an increasing amount of most offensive discharge. She had been rapidly losing flesh, colour, and strength, and, in fact, presented the appearance and ordinary symptoms of malignant disease of the uterus. The cervix, however, was perfectly healthy, the uterus was enlarged, the anterior wall being hard and nodular, and the right ovary was large and tense. The sound passed easily  $3\frac{1}{2}$  inches forwards, and the uterine canal was quite smooth. Dr. Fenwick therefore diagnosed the case as one of degenerating fibroid and performed hysterectomy by abdominal section in the ordinary manner. The patient made an uneventful recovery, and rapidly gained flesh and strength, and her colour became normal.

The specimen showed that the anterior wall of the uterus contained two fibroids of about equal size, measuring  $3\frac{1}{2}$  inches across, and 2 inches from above downwards. Each fibroid was enclosed in a separate capsule, the upper one being uniformly thick all round. At the lower part of the lower fibroid necrotic degeneration has commenced, and the pus and debris were escaping from the small cavity through a narrow opening into the uterine canal, just above the internal os. The case was interesting not only because the specimen was so unusual, but because the symptoms so closely simulated those of malignant disease of the uterine body. It was also noticeable that the right ovarian artery which was obstructed by the fibroid outgrowths at the fundus was greatly thickened, its muscular coat being much hypertrophied, and the right ovary was converted into a large blood cyst, containing eight ounces of black blood, the tube also being swollen and thickened. The left ovarian artery was quite normal in calibre, and the left ovary and tube were perfectly healthy, and Dr. Fenwick emphasised the fact that where the ovarian artery entered the fundus on the left side the area was free from any fibroid outgrowth.

After some remarks from Dr. MACNAUGHTON-JONES, the specimen was referred for a pathological report, on the motion of Dr. Purcell, seconded by Dr. R. T. Smith.

The PRESIDENT said that their Editor had left on the table a copy of Dr. Macnaughton-Jones' "Diseases of Women," and particularly wished to draw attention to the beautiful illustrations in it of glandular endometritis bearing on Dr. Alexander's communication.

#### ROYAL ACADEMY OF MEDICINE IN IRELAND. SECTION OF MEDICINE.

MEETING HELD FRIDAY, DECEMBER 9TH, 1904.

DR. HAWTREY BENSON in the Chair.

#### LIVING EXHIBITS.

DR. COLEMAN exhibited a case of (a) Congenital Bulbar Paralysis.

DR. F. C. PURSER said he had to thank Dr. Coleman for having given him many opportunities of examining the case in hospital. Bulbar paralysis was certainly an uncommon disease, occurring in young children. The first time he saw the case he thought it could only be an anterior poliomyelitis, affecting the nuclei in the medulla oblongata, and so causing symptoms of paralysis, especially of the seventh, ninth, and twelfth nerves, but on thinking over the case he could not recall having seen or heard of such a condition, and so tried to think of any other explanation. He then

thought it might be due to a thrombosis or other vascular lesion, but thought it was improbable that the symptoms would be so localised, and also for that same reason such things as tumour, gumma, &c., were excluded. Another idea was that it was a pseudo-bulbar paralysis. There were cases of congenital or infantile bulbar paralysis recorded, but they differed in this respect: that there was a strong family history of it having occurred in more than one member of the same family, the parents also having been blood relations. Also the upper part of the face was as much affected as the lower. The observers attributed it to a hereditary tendency to early atrophy of the nerve nuclei, and a failure in the perfection of their development. Whether there were any pathological grounds for these theories or not, he did not know. The theories which he would submit himself were—first, an affection of the nerves themselves, rather than the nuclei from which the nerve fibres arose. In this connection he might mention a case of bulbar paralysis which had occurred suddenly in a young person after laryngismus stridulus. It might only have been a coincidence, but both were possibly caused by toxins. Secondly, a primitive myopathy may have affected the involved muscles. He certainly had never heard of such, but a hereditary disease had to begin somewhere.

DR. COLEMAN in reply, thanked Dr. Purser for his very interesting and instructive communication.

DR. COLEMAN also showed a case of (b) Pityriasis Rubra.

The CHAIRMAN said the case reminded him of a case of pityriasis rubra which had been an exact *fac simile* to that one, but there was no history of a preceding eczema. The chief point about the case had been that it got well under four or five weeks' treatment by arsenic.

DR. O'BRIEN said that the characteristic rash of pityriasis rubra was very abrupt, but in this case it had taken a considerable time to spread, which would contra-indicate pityriasis rubra.

DR. KIRKPATRICK took it that Dr. Coleman differentiated this case from an ordinary case of pityriasis rubra, as he looked on it as secondary, as it came on subsequent to psoriasis. He wished to know if Dr. Coleman thought the treatment of the psoriasis had anything to do with the causation of the pityriasis rubra, or exfoliative dermatitis. He thought it a pity to use the term pityriasis rubra, which had a definite connection with a form of disease, for conditions which were not similar to it, and he considered that the term exfoliative dermatitis described it better.

DR. COLEMAN, in replying, said that the only treatment used was calamine lotions and olive oil, or olive oil and lime water: simple emollients. He had not given arsenic on account of the acuteness of the case. There had been a distinct improvement during the last week. He had had a case of primary pityriasis rubra which had got well under similar treatment. As to diagnosis he thought that as the case had no other symptoms but universal redness and thin scales, they were sufficient to exclude any other skin disease but pityriasis rubra. It was not very essential where the disease began, as it might begin anywhere, and spread rapidly over the whole body. That being the case you would expect it to start from the psoriasis lesions, which it had done. He agreed with Dr. Kirkpatrick that exfoliative dermatitis would be a better term.

DR. T. P. C. KIRKPATRICK showed a well-marked case of Ichthyosis Simplex. The patient, a male, *æt.* 23, stated that the condition had been present as long as he could remember, but that none of his family ever had any similar condition. The patient has been recently infected with primary syphilis, and is now developing an extensive secondary pustular eruption on the trunk and limbs. The ichthyotic condition of his skin has not caused him any serious inconvenience.

DR. O'BRIEN said he had a patient, a man, *æt.* 26, with all his organs healthy, who had suffered from the condition for fourteen years. Three brothers had eczema, and two sisters. He thought these cases could be improved, but not cured.

DR. KIRKPATRICK, in replying, said it was of interest

to see whether the accompanying syphilis would have any effect on the disease, as in cases of ichthyosis associated with small-pox.

Dr. F. C. PURSER showed a Peculiar Deformity of the Spine, with nervous symptoms—a girl, æt. 8, who was born with spina bifida. Marked deformity of the spine remained, causing muscular wasting, anæsthesia, lost knee-jerk, and trophic sores on the left leg.

Dr. O'CARROLL reviewed three cases of Syringomyelia which he had formerly had under his care, and gave an account of the symptoms of a fourth, which had died recently. In this case the appearances were practically those of amyotrophic lateral sclerosis, with marked wasting in the muscles of the upper limbs, and some clawing of the hands. The remarkable feature of the case was the absolute absence of anæsthesia of any kind, though frequently searched for, coupled with tenderness to pressure of the second and third dorsal vertebræ and of the right second rib, which had led to a diagnosis of disease of those vertebræ inducing a compression myelitis. The cavity in the cord extended through the cervical and dorsal regions, was about 5 mm. in average diameter, and in some places was double.

Dr. COLEMAN said they had to thank Dr. O'Carroll for having thrown a lot of light on this disease, he having first described it in this country. He thought that the case would not have been absolutely diagnosed as syringomyelia from the symptoms, and he believed that more of these cases would be discovered if thorough *post-mortem* examinations were made, as Dr. O'Carroll was in the habit of doing. He himself had had a case of the disease under observation for the last ten years. It began when the patient was a boy of ten, and the muscular symptoms were then well marked, with the characteristic dissociation of sensations. The anæsthesia and sensory symptoms were present in the arms now exactly as they were ten years ago.

Dr. THOMPSON said the history of the case showed the difficulty of making a positive diagnosis, and the necessity for making thorough *post-mortem* examinations.

Dr. O'CARROLL, in replying, thanked those who had discussed his paper. He said he was under the impression that a fair number of those cases had spastic phenomena in the lower limbs, and the two other cases he had examined certainly had them. The case Dr. Coleman and he had shown was now in the Incurable Hospital, and doing well. He had well-marked spastic phenomena. In fact, he thought that syringomyelia might present a picture like a compression myelitis, except that it was uneven, and had the peculiar sensory phenomena and trophic disturbances, such as whitlows, perforating ulcers, talipes, &c.

#### SECTION OF OBSTETRICS.

MEETING HELD FRIDAY, DECEMBER 16TH, 1904.

The President, Dr. ALFRED SMITH, in the Chair.

THE business of the Section was adjourned until the next stated meeting.

#### EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DECEMBER 7TH, 1904.

PROFESSOR JOHN CHIENE, C.B., President, in the Chair.

DRS. BURN MURDOCH and STUART McDONALD showed specimens of "Biliary Cirrhosis" in a young child.

Mr. SCOT SKIRVING showed (1) a simple form of coin-catcher; (2) old stereoscopic photographs of cases operated on by Professor Spence, Professor Syme, and others; (3) specimen of congenital syphilitic disease of the knee-joint.

Mr. MILES showed specimens of kidneys removed for calculous pyonephrosis, calculous hydronephrosis, and tuberculous disease.

Mr. CAUD showed Luy's urine separator with examples of urine obtained from each kidney.

Mr. A. G. MULLER read a short paper, entitled THE TOILET OF THE ANUS.

in which the risks of contamination of the fingers and of adjacent parts from an insufficiently cleansed anus were mentioned, and a simple method of purification described. Whatever means were adopted, the hands, especially the nails, were liable to infection, and required careful washing and disinfection after the anal toilet. Many local ailments were due to lack of cleanliness, particularly of the hands. Among these pruritus ani, abscess, piles, and fissure were mentioned. In many cases simple cleanliness did much to alleviate such conditions; in particular small rectal injections of cold water after washing were most useful both as palliatives for, and prophylactic against, hæmorrhoids.

In commenting on the paper, Dr. ALLAN JAMIESON spoke of the value of nightly injections of thin warm starch, to which a little liquor, bismuth, had been added in the treatment of pruritus ani.

Dr. AFFLECK spoke of the necessity of seeing that nurses were properly instructed in the importance of cleansing the parts in cases of typhoid in particular, and Dr. CHURCH, of the importance of purifying the nozzles of syringes used in giving enemata, &c., before introducing them into the bowel.

Professor D. J. CUNNINGHAM gave a lantern demonstration of some researches he had made on THE FORM OF THE STOMACH.

His slides were photographed from preparations in which the stomach and other viscera had been hardened *in situ* by formalin. The specimens shown confirmed, and to some extent supplemented, the recent observations of Professor His. It seems that the stomach normally lies more or less horizontally, not vertically, the greater curvature being somewhat anteriorly placed, close under the parietes. In formalin-hardened subjects, certain kinks and indentations are not infrequently found in the stomach. These are probably physiological, not the results of the hardening process. They to some extent coincide with Cannon's observations on the movements of the stomach of the cat when studied by X-rays. In some preparations the so-called hour-glass contraction of the stomach was shown, and the view was expressed that this was not a pathological lesion, but an appearance due to the fact that death had occurred during the occurrence of active peristaltic waves. The main point in Dr. Cunningham's communication was an attempt to show that the stomach was by no means an inert, passive sac or reservoir, but that it was an active, muscular organ which might assume manifold shapes, and that some of these, persisting after death, had been ascribed to a morbid process, whereas they were physiological.

A long discussion took place on Dr. Cunningham's demonstration, the general opinion being that there was not sufficient evidence that the changes he described actually occurred during life, and that it was possible that some of them might be agonal, or due to the action of formalin.

Mr. THOMSON remarked that in operating on the abdomen the stomach was usually relaxed, and that peristaltic waves were rarely seen.

Mr. STILES pointed to the frequency with which visible peristalsis occurred in congenital hypertrophy of the pylorus.

Dr. HARVEY LITTLEJOHN doubted whether if death took place while the stomach was acting the spasm would not at once relax. Except for the rare case of cadaveric spasm, death was followed by relaxation of muscular fibres. On the other hand, as rigor mortis set in muscular movements might take place, *e.g.*, the numerous intussusceptions so commonly met with in children.

DRS. RITCHIE, AFFLECK, and GREENFIELD discussed the recognition during life of the exact shape of the stomach by percussion, the latter emphasising the necessity for percussing down the mid-axillary line.

Dr. WATERSTON recounted some attempts he had made to secure X-ray photographs of the human stomach after large doses of bismuth had been swallowed.

Dr. RAINY spoke of the radiography of the organ in children.

Drs. Black, Caird, George Hunter, and Gulland also spoke.

## France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, December 18th, 1904.

### FOREIGN BODIES IN THE NOSE.

FOREIGN bodies in the nasal fossæ are generally of small volume, which children introduce for amusement; they are also frequent in hysterical and insane persons. Buttons, pearls, beans, peas are those habitually employed. Foreign bodies coming from the pharynx can enter the nasal fossæ from behind. This accident has happened in cases of paralysis of the velum; but even where this is intact, the same may occur through the efforts of vomiting. It is thus that can be explained the presence of worms in the nose as has been sometimes observed. When these are of small volume they are often expelled by sneezing or of their own accord. When they sojourn, they are generally to be found at the anterior extremity of the turbinated bone or in the lower outlet. They can remain *in situ* a long while without producing any inconvenience other than an exaggerated secretion. Certain of these bodies, as beans or peas, may swell to a considerable extent, blocking up the whole aperture.

The symptoms provoked by the presence of a foreign body are at first an increase of the secretion of the pituitary membrane, but soon this latter becomes inflamed and the secretion is muco-purulent. This happens especially when the body is hard and embedded in the fossa. Ulceration of the mucous membrane is the result, which may end in its perforation. In such a case blood is mixed with the secretion. Sooner or later the secretion becomes foetid and the discharge is abundant.

The diagnosis of foreign bodies in the nasal fossæ is easy when of recent occurrence and before awkward attempts at extraction have been made. The stilette is the best instrument to detect the nature of the body, but it is well to apply to the mucous membrane a solution of cocaine before proceeding to expose; it facilitates the operation. If the instrument reveals a hard body the idea of a polypus can be excluded; it is a case of a foreign body, rhinolith, sequestrum, or osteome. The necrosis produced by the existence of a sequestrum causes extreme foetidity of the discharge, which does not exist in cases of foreign bodies.

As to treatment, in cases of adults or intelligent children, the blowing of the nose vigorously may be recommended and sometimes succeeds. The insufflator of Politzer may be tried in young children, but the nasal douche should not be employed as the jet of water may penetrate into the middle ear by the Eustachian canal.

If these simple means fail, what is to be done? asks Dr. Meiner. A bent stilette can be gently passed in and passed behind the obstruction, and extract it, or at least stir it so as to render it possible to seize it with forceps, or it can be pushed backwards into the pharynx, taking the precaution of passing the index finger of the left hand behind the posterior opening. In this way M. Menier, by means of a catheter, extracted a boot button from the nose of a child æt. 3, and which had been introduced into the nose two months previously.

Unfortunately all these operations provoke abundant hæmorrhage, which must be stopped before continuing the attempts at extraction. In my next letter I propose summarising the treatment of "Foreign Bodies in the Ear."

THE Council of the London and Counties Medical Protection Society, at its meeting on December 9th, resolved that on and after January 1st, 1905, an entrance fee of ten shillings be charged to all new members joining the Society.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 17th, 1904.

At the Ophthalmological Society, Hr. Greef reported on an examination he had made at the request of the Government on the sight of pupils in the schools. The inquiry, which had been carried out by himself and his assistant, had been an exhaustive one, and included enumeration and classification of all diseases met with, and measurements of light, height, and slope of desks and the distance between the desks and the seat, &c. He proposed that before the erection of any new schools the plans should be laid before a sanitary commission which should be empowered to order any alteration deemed necessary.

As regarded anomalies of refraction, he found that myopia was increasing in number and degree in all classes, and especially in the middle grades. Between the worst and the best lighted gymnasia there was no marked difference as regarded numbers, but as regarded degree, the worst lighted showed the highest degrees of the abnormality. A table prepared by Cohn showed that near eye work and not age played the chief part in its production.

He found myopia:—

In the Volksschulen	1.4 per cent.
In the Elementary Schools	6 per cent.
In the Higher Girl Schools	7 per cent.
In the Middle Schools	10 per cent.
In the Realschulen	19 per cent.
In the Gymnasium	26 per cent.

He explained short-sightedness as a process of stretching at the fundus oculi, and that the process was more common in early life. Schillnez looks upon it as a racial question. Germany had the most myopics, then came France, and then England. According to the speaker's views, however, it depended more on the habits of the race; as the sclerotic was stronger then the other body tissues were also strong. Sports and bodily exercise tended to a diminution of short-sightedness.

Hr. Hirsch, in the discussion that took place, said that the property of stretching was not limited to early life. Amongst 650 writers he found 245 myopics, of whom only 45 had been myopic during school life, so that they must have acquired their myopia by later near eye work.

Hr. v. Michel had examined the eyes in the Erlanger Gymnasium for myopia thirty-five years ago, and in the upper classes had found 88 per cent. of myopics.

At the Medical Society Hr. Grawitz related a case of LEUCÆMIA TREATED BY X-RAYS.

The patient, a man, æt. 54, came to him at the commencement of October in a very miserable condition. The proportion of red to white blood corpuscles was almost 1 : 1, the latter almost exclusively lymphoid cells. The liver and spleen were both swollen. After twenty-three Röntgen illuminations the general condition of the patient had not only distinctly improved, but examination of the blood showed only a slight deviation from the normal. Both liver and spleen were considerably reduced in size. Possibly the lymphoid cells were directly dissolved by the rays, but to determine that a quantitative determination of the urea was necessary. The case must not be looked upon as cured, but the influence of the X-rays was of therapeutic and biological interest.

Hr. Levy-Dorn showed a man who had had pseudo-leucæmic glandular tumours, and who had been treated by the X-rays. A distinct improvement had taken place in the general condition. Care should be taken when deep action was required not to bring the lamp too near the part to be acted on.

At the Free Society of Surgeons Hr. v. Schneider offered a contribution to the

### SURGERY OF THE PANCREAS.

A woman, æt. 43, had had repeated attacks of biliary colic, and again in August, 1902; in connection with this pneumonia developed, then she had pains in her left side,

and four weeks later fever, diarrhoea, pain and a tumour at the arch of the left rib; exploratory puncture gave pus. The speaker opened the abscess and came into a cavity that reached to the spine and contained great necrotic pieces which proved to be gangrenous pancreatic tissue.

After a time a fæcal fistula formed, which, however, closed spontaneously, and in the course of ten weeks recovery took place. A year later fresh attacks of colic came on and a year and a half later transient sugar was found which, however, soon disappeared. There was still tenderness on pressure on the epigastrium, which pointed to chronic pancreatitis. Probably there was a connection between the pancreatic disease and the gall-stones.

The second case was that of a young man who was struck by a shaft in the epigastrium, and who then fell unconscious; he vomited afterwards. When seen the following day the man had pain, but the general condition was good. The day after, however, he vomited, and the pulse grew worse. Laparotomy was performed, and a transverse rent found in the head of the pancreas. There was distinct necrosis of fatty tissue. After arrest of the hæmorrhage the cavity was tamponaded. The peritonitis, however, went on, and the patient died. The autopsy revealed no injury of any other organ, the case was one, therefore, of an isolated rupture of the pancreas. The fatty necrosis must have been secondary.

Hr. Riese, who took over the first case soon after the operation, was of opinion that the greater part, if not the whole, of the pancreas had necrosed and been cast off.

Hr. Kôte mentioned a case where a patient had diabetes, and died in diabetic coma seven years after operation for necrosis of the pancreas. After death, it was found that the whole of the head of the pancreas had been retained. Whether the diabetes had anything to do with the necrosis of the pancreas was very questionable.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 17th, 1904.

### ANGINA ULCEROSA.

At the Gesellschaft, Escherich demonstrated two cases of angina ulcerosa that had been diagnosed as diphtheria before coming to hospital.

This is not an uncommon blunder, and practitioners have good reason to justify the diagnosis when this occurs, as the membranous deposit on the fauces at the commencement of the disease is not at all unlike diphtheria. It is only after a careful examination of the deposit with a microscope, or after a few days have elapsed to allow of the deposit clearing off, when crater-like depressions are observed and loss of substance demonstrated, that it can be proved that it was ulcerative in character and not a simple exudation. He showed two other cases with a deposit that had continued for some time without fever or swelling of glands, but no diphtheritic bacilli could be found in the deposit, except those described by Vincent, which were of a fusiform shape and innocent in character.

### BARLOW'S DISEASE.

This is a commonly recognised disease on the Continent now. Prior to Barlow's description in 1883 the disease was known as "acute rachitis," occurring in the first year, or about the fifth month. The disease is closely allied with scorbutus in the adult, and is therefore dependent on the proper nutrition of the infant, occurring in children fed on artificial preparations, boiled milk, &c., &c. It is not really want of food but rather over-feeding with innutritious food. As the want of fresh vegetables induces scorbutus, so in the case of the infant a lack of fresh milk produces a deleterious condition in the child, as swelling around the epiphyses, hæmorrhages into the subcutaneous tissues, &c., &c.

The child Escherich showed to the members was eight months old, and had been fed on "Biedert's"

artificial cream. It had been sent into the hospital with a diagnosis of spondylitis.

The hæmatoma over the epiphyses of the femur, speno-maxillary bones, and orbit pointed to some justification for the title, but closer inspection, with change of food, soon convinced him that malnutrition was the real factor in the morbid condition. Fresh milk was all that was necessary to effect a cure.

### OVARIAN CYST.

Wechsberg gave the members an interesting account of a cyst which he had removed from a woman, æt. 72. He considered the cyst to be a dermoid which may have been there for some time past, as he could discover no cause beyond a sort of chronic hyperplastic perihepatitis, which had led to a reduction of the liver, though not in the sense of a hepatic cirrhosis. There were no signs present to show how these hepatic changes had come about.

### SPECIFIC AGGLUTINATION.

Schick reported an experiment carried out at the scarlatina hospital laboratory in which a child after one of Bassini's operations for hernia had a large abscess that formed over the new inguinal canal. The streptococcus taken from the abscess formed a specific agglutination with Roser's serum, which is reputed to be an antidote for scarlatina. It was presented in the proportion of one to four thousand. A few others have obtained a similar result with this serum.

### PREGNANCY AND PUERPERAL INVOLUTION.

Halban read a paper on the changes of the uterus in pregnancy, which he divided into physiological and chemical, some of which were benign, others malignant. Of the former, decidual formations, hypertrophy of the uterus, freeing of the vagina, and mammary changes were natural sequences, but renal œdema, pigmentation, and hæmatic changes were always fraught with danger.

According to the experiments of Goltz and Ribbert, the chemical substances in the blood are the real origin of the changes, and are conveyed to the placenta and fœtal organism on which they act. The speaker agreed with the theory, as he had frequently had opportunities to examine uteri and invariably found the fœtus hyperæmic as well as the peri-uterine vessels, muscles, &c., greatly enlarged and distended with blood. Decidual formation was not observed in the experiments, but the mucous membrane had all the characteristics of menstrual changes. In the mammary gland a powerful reaction took place at birth. In the fœtus these changes are also present in sympathy with the mother, as in both mother and child milk will be found in the breast if a female, while hæmorrhage may be met with in both child and mother. It therefore appears that the toxic component of pregnancy passes over the fœtus as well as the mother, as hyper-leucocytoses, nephritic changes, and increase of fibrin were present in both. It seems that this toxin is derived from the placenta and from the epithelial chorion as a secretion common to the two lives, but as soon as the cleavage takes place these symptoms, both in mother and child, cease, and involution commences. The meeting of the spermatozoon and ovum determine the placenta. These fœtal changes are not confined to the female sex, as the "witch milk" of the placental toxin reacts on the prostate of the boy *in utero*, which gradually diminishes after birth, and is always much larger at birth than in children many months older. It is estimated that these active changes in fœtus and mother take place most markedly about the end of the eighth lunar month, when the breasts of the female and the prostate of the male will then be found much larger than in children many months older. We conclude, therefore, that the toxin is equally potent in both sexes alike. In eclampsia, which is connected with the separation of the placenta, the toxin is present in the fœtus in as great a quantity as in the mother.

In the discussion Frankl said that he had made many examinations of the round ligament of the uterus, which is the rudiment of the conus inguinalis of the animal, and constantly found the striated fibres greatly increased and the whole ligament thickened. The

same thickening took place in the foetus in the ninth or tenth lunar months, which is in perfect accord with Halban's theory. He had also observed the great size of the prostate in the male foetus, and would add that the vesiculæ seminales, as well as the pons ampullaris and vas deferens, are also enlarged.

Knöpfelmacher said that he had brought the enlargement of the breasts in the foetus before this meeting two years ago, and suggested then that the milk in the mother was excited by a ferment from the placenta.

Hofbauer agreed with a ferment from the placenta exciting the milk, but doubted the hypertrophy of the genitals in the foetus as these were met with, but were not constant.

## The Operating Theatres.

### ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.

OPERATION FOR CONICAL CORNEA.—Mr. H. B. GRIMSDALE operated on a case of conical cornea. The patient, a woman, æt. 46, had been in hospital for some time previously owing to ulceration of the apex of the cone. With the galvano-cautery Mr. Grimsdale cauterised an area surrounding the apex about 4 mm. in diameter, and thence made a superficial burn to the nearest point of the periphery of the cornea. He then proceeded to cauterise the centre of the circular burn rather more deeply, but, owing to the thinness of the cornea, this membrane was perforated unintentionally before the required depth had been obtained. Mr. Grimsdale said that there were two methods of dealing with such cases: either to produce a scar over the weak area, which allowed the protrusion of the cornea, and thus by supporting it to reproduce the normal curvature, or to excise the weak point of the cornea, and to reform at once an almost normal structure. To deal with this latter method first, it had great advantages; the resulting scar was almost invisible, a single operation sufficed, and often no correcting lenses were necessary, but the risks of the operation were so great that it was rarely justifiable to employ it; a very large open wound was left in the cornea after the excision of the apex of the cone; it was hardly possible, he said, to close this with sutures, and the risk of immediate infection and total loss of the globe was very great. Further, many patients who escaped this suffered prolapse of the iris, and some sympathetic ophthalmia; therefore, he thought, although the results of a successful operation by this method were very brilliant, and better than those which it was possible to gain by the cautery, yet the average results by the latter method were superior. In such a case as the present, where the conjunctiva was obviously not aseptic, it would be under all circumstances unjustifiable to allow the patient to run the risk of an open perforated wound of the cornea. As regards the method by the cautery, he pointed out that there were several modifications; that which he had employed was practically the method of Sir Anderson Critchett. Sir Anderson recommended that the burn of the cornea should be made in successive rings, increasing in depth towards the centre, a form which he compared to a target. In this patient, Mr. Grimsdale said, it had not been possible to follow this method in all points; owing to the thinness of the cornea, the bull's-eye of the target could not be burnt to the depth which had been wished. The accidental perforation entailed a longer convalescence, but probably no other

inconvenience. In extending the burn from the target to the periphery he was departing from Sir Anderson Critchett's method and adopting one recommended by foreign surgeons. The idea was that this promoted the growth of vessels from the surrounding conjunctiva to the central scar, which was therefore vascularised early, and became more stout and resistant. Such a scar necessarily interfered with vision, occupying as it did the centre of the cornea, and it would be necessary at a later date to perform an optical iridectomy to make an artificial pupil to allow useful vision, and probably further to tattoo the central scar so as to prevent the passage of diffused light; this second operation, he said, would not be undertaken for some months, until the curvature of the cornea was re-established.

### ST. BARTHOLOMEW'S HOSPITAL.

OPERATION FOR STRANGULATED FEMORAL HERNIA IN A MAN.—Mr. McADAM ECCLES operated on a man, æt. 43, a German baker, for right strangulated femoral hernia. The patient had had a previous attack of apparent strangulation three days before, but the contents of the sac had then been reduced by taxis. He was subject to chronic bronchitis and had a severe cough, during a fit of which six hours previous to operation the hernia became strangulated. In spite of the lung trouble, Mr. Eccles decided to operate rather than to employ taxis. He advised that chloroform should be selected as the anæsthetic, and this the patient took well. On the sac being opened slightly, blood-stained fluid escaped; within the sac were found two short loops of small intestine lying side by side and tightly gripped by the femoral ring; each was deeply congested, showing marked evidence of strangulation. The stricture was divided and both loops gently drawn down, when it was seen that the constriction had been such as to distinctly indent both loops at the level of the ring, and that the loops belonged to separate parts of the small intestine, a portion of non-congested bowel lying between them. After this inspection both were returned within the abdomen. The sac was dissected up, ligatured flush with the parietal peritoneum, and the femoral ring closed by silk sutures passed from the deep aspect of Poupart's ligament into the origin of the pectineus muscle. Mr. Eccles remarked that there were several factors of interest in the case. The patient, he pointed out, was an undersized man and a baker, both of which circumstances favoured the incidence of femoral hernia, seeing that the occupation leads to severe strain in a stooping position. Femoral herniæ in men, he considered, only account for about 2 per cent. of all protrusions. Operation, he said, was undertaken first because strangulation had already once occurred, and, secondly, from the fact that strangulation by Gimbernat's ligament is apt to be so severe as to rapidly damage the intestine beyond recovery; thirdly, the operation would be a comparatively simple one on account of the thinness of the patient; so that, in spite of the lung trouble, operation seemed to be the least risky procedure. The exposure of the contents of the sac demonstrated the uncertainty that there always is in strangulated hernia as to the exact viscera that will be found nipped. In this case the decidedly rare condition of two separate knuckles of gut strangulated side by side by the same constricting band was found. It was obvious, he thought, that taxis would have been wholly unavailing

both on account of the presence of the two portions of bowel and of the extreme tightness of the ring. The advantage of a close examination of the intestine after division of the stricture was always great, for it was extremely likely in femoral hernia—and particularly so in a male subject—that the almost knife-like edge of Gimbernat's ligament should tend to deeply groove the bowel, which is becoming increasingly congested by the imperfect return of venous blood from its coats, whilst the arterial influx continues.

The bronchitis was not aggravated by the anæsthetic and the wound healed very satisfactorily. A fortnight after operation the patient had an attack of typical lobar pneumonia ending in crisis, but the violent coughing did not cause any giving of the closed right femoral ring.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, DECEMBER 21, 1904.

#### THE LONDON HOSPITAL FUNDS, THE HOSPITALS, AND MR. STEPHEN COLERIDGE.

In a series of articles we propose to criticise the relations of the hospital funds to the hospitals, the medical profession, and the public. The high esteem in which we hold these distributing agencies has been so fully and so frequently professed that there is no need to insist upon the point further. Indeed, it is only the feeling of sincere regard for the future of the Funds that leads to the inquiry whether they are not open to improvement in various directions. The fact that the most important, although the youngest of these Funds, is under the presidency of King Edward VII renders it absolutely certain that every complaint will be carefully and impartially investigated, and that nothing essentially unfair or unjust will be permitted to mar the doings of the Funds. With that conviction well in sight we shall have no hesitation in speaking out our views clearly and impartially. At the outset it may be well to remark that it is extremely difficult, if not impossible, to obtain full information on all points, and if

any of our details should fall short of accuracy we shall be open to correction. The matter, however, is essentially one of principles, and as such must ultimately be settled on those lines. For years past we have asserted in THE MEDICAL PRESS AND CIRCULAR that the public have a right to be informed of the principles upon which grants are made to medical charities. Hitherto the Funds have maintained a silence upon those points as absolute and autocratic as though the administration were in Russia instead of England. Surely in the administration of huge sums of trust money the executive councils of the Funds should proceed on lines of action definitely drawn up and at all times accessible for public information. Our first claim, then, is that the policy of the hospital funds should be openly declared, and that definite information on detailed points of administration should be obtainable by any private citizen. The necessity of some such condition was illustrated last week at the Mansion House annual general meeting of the Hospital Sunday Fund, under the presidency of the Lord Mayor, Sir J. Pound. The Hon. Stephen Coleridge, on that occasion, raised the question of the diversion to medical schools of funds contributed to the hospitals. The speaker was perfectly within his rights in drawing attention to the point, which obviously has a most important bearing on the proper conduct of medical charities. With Mr. Coleridge and his views upon vivisection we have no sympathy whatever, but that fact does not exclude him either from courteous treatment or from an opportunity for expressing his views generally in the columns of THE MEDICAL PRESS AND CIRCULAR. Let us see how he and his friends were treated by the Hospital Sunday Fund. His seconder, the Rev. Mr. Lewis, pointed out an instance of alleged wrongful diversion of funds: £7,000 had been spent by the authorities of the London Hospital for a sports ground for students. The London Hospital has an average annual grant from the Sunday Fund of some £5,000. Any subscriber to that Fund, therefore, is competent to raise the question at a general meeting as to how the money thus awarded is spent by the hospital. Surely the Hospital Fund has a policy on a point of such vast importance to hospital administration. Either it is right or it is not right to allot money subscribed to medical charities upon medical schools. Instead of any official declaration from the Sunday Fund, however, the defence of that body was undertaken by the Hon. Sydney Holland, chairman of the London Hospital, a subscriber to, but not an official of, the Sunday Fund. We have the greatest respect for the conspicuous kindness and genuine disinterested philanthropy that characterises Mr. Sydney Holland. As counsel for defence, however, or as the expounder of a calm judicial analysis of facts and principles, we should regard him as hopelessly out of place. His speech at the Mansion House was, indeed, a warning to all gentlemen who trust to their hearts rather than their heads in

public discussion. He described the remarks of Mr. Lewis as "uncharitable sneers," and said it would have been more generous had the clergyman written him beforehand. "With regard to the sports ground," he continued, "they had the money to invest, and they certainly did not begrudge the sum paid for it. It would, perhaps, surprise Mr. Coleridge and his followers to know that he could sell the sports ground any day for £10,000." All this leaves the main question of Mr. Coleridge unanswered. The point was the right of the hospital to devote charitable funds to the purchase of a sports ground, not as to whether the London Hospital was accumulating money and making sound investments. Nor did Mr. Holland improve his position or that of the Sunday Fund by admitting that the London Hospital authorities had refused Mr. Coleridge's subscription, because it was not sent with the view of doing any good to the hospital (*Daily News* report, December 17th, 1904). Then he went on: "Mr. Coleridge says, 'This money is given to medical colleges which publish no accounts.' Well, we do not supply Mr. Coleridge with a copy of our accounts, because we know the purpose for which he wishes to use them." We submit that such an attitude is insolent and unwarrantable on the part of any hospital committee. Moreover, Mr. Holland was silent when asked whether the accounts of the medical school were sent to any subscriber. The end of this most unsatisfactory discussion was to defer the matter, on the motion of Sir Henry Burdett, until the recently-appointed commission had presented their report. The results appear to show that the Hospital Sunday Fund, although governed by a small and absolutely autocratic executive, has either no decided views with regard to the proper disposition of hospital funds, or, having such views, it is not prepared to announce them in public. Why should not all hospitals, great and small, and all hospital reformers be represented on the executive of the Hospital Sunday Fund? At present the council is a handful of persons deeply interested in particular charities and systems of charities. Its constitution is directly opposed to the enlightened and democratic tendencies of the age.

#### ETHER AND THE BLOOD.

THE examination of the blood is coming more and more to be regarded as an essential part of the clinical investigation of the condition of a patient. Not alone in medicine and diseases affecting the blood, primarily or secondarily, is it thought necessary to have an accurate idea of the condition of the blood, but in surgical affections, and as an indication for surgical operation, its state is regarded as of importance, especially as there is no earlier sign of inflammation than the sudden occurrence of leucocytosis. In order, however, to be able to make use, for diagnostic and prognostic purposes, of the facts gained by examination of the blood, it is necessary to have accurate knowledge of the changes brought about

in the blood by the administration of certain drugs. Of these by far the most important are the common anæsthetics, for their action, if not taken into account, is likely seriously to mislead our judgment on the changes following surgical procedure. It is necessary too, that the physiological action of the usual anæsthetics should be thoroughly understood, and though the action of ether and chloroform on the heart and lungs has received much study, their action on the blood is not known as it should be. During the past few years, however, many investigators have devoted themselves to this field of study, and already we are in a fair way to definite knowledge. Drs. Anders and Boston, of Philadelphia, have published a series of observations (a) on the effects on the blood of the administration of ether in rabbits and in man. In the case of man they have only made use of patients who had not been prepared, either by purging or fasting, for the anæsthetic, as such preparation of itself causes certain changes in the blood. The results obtained are very uniform, and allow certain fairly definite conclusions. The first change noted is a decrease in hæmoglobin, amounting approximately to 10 per cent. during the first twenty minutes of the anæsthetic state. The hæmoglobin reaches its lowest ebb about twenty-four hours after administration of ether, and thereafter tends to return to the normal. This decrease of hæmoglobin explains what has long been known as a clinical fact, that severe anæmia is contra-indicative to prolonged administration of an anæsthetic. Various surgeons have recommended various minima of hæmoglobin, from 30 to 50 per cent., under which they recommend that major operations should not be undertaken. Side by side with the decrease of hæmoglobin, and proportional to the degree of cyanosis accompanying administration, is an increase of the red blood corpuscles. In all cases following on the use of ether there were definite degenerative changes in the red blood cells, mostly associated with the abstraction of hæmoglobin. A fairly constant result, also, of ether narcosis is marked leucocytosis; in some cases the leucocytes were doubled in number, but in all the cells were increased in their normal proportions to each other. This is in marked contrast to what occurs in inflammatory conditions, where the great increase is in the lymphocyte variety.

#### THE REGISTRATION OF MEDICAL STUDENTS.

THE long and somewhat heated debate on the proposal to establish a compulsory register of medical students which took place at the last session of the General Medical Council deserves careful study. The point at issue was sufficiently important in itself, but the mere subject-matter of the debate sinks into insignificance when the larger questions of motive and method are brought under review. The issue really was two-fold—

(a) *Therap. Gaz.*, November 15th, 1904.

namely, whether a Students' Register should be formed, and whether the Council should charge a fee for admission to the Register. It is well known that the finances of the Council have been for a long time past in an unsatisfactory position. The work of the Council has grown, its sessions are longer, and its inspections of examinations are more frequent and thorough. All this means increased expense, and unless funds are forthcoming to meet these expenses not only will the Council be unable to extend its field of operation, but it will be forced seriously to curtail its present undertakings. The matter, then, resolves itself into the following alternatives: Shall the Council grow in power and influence until it becomes the governing body of the profession in deed as well as in name, or shall it sink into the position of an academic body whose function is to keep the Register, to superintend medical education, to record pious opinions, and to furnish the Privy Council with information about the profession when asked to do so? These alternatives may be put in another way. The General Medical Council is the only power-possessing body in the Profession on which the general practitioner has any representation, and, absurdly inadequate as that representation is, the fact remains that it is only through the Council that the general practitioner has any chance of making his views known and his weight felt. Is the general practitioner, then, to be shorn of the modicum of power that is passing into his hands through the increasing influence of the Council, or is the profession in the future, as in the past, to be governed by a number of interested corporations and big-wigs who care little or nothing for the toiling rank and file? This question is contained in the nutshell of students' registration. By extending its power of control over the avenues of approach to the profession, the advocates of students' registration contend that the Council, by establishing such a Register, would gradually be able to define the standards of preliminary education which a student should attain before beginning the study of medicine. Moreover, by instituting the modest fee of one pound for such registration, the depleted exchequer of the Council would be replenished sufficiently to allow of extended work and more complete development. The only alternative means by which money can be raised is either by obtaining an improbable grant from Parliament, already refused; by levying an annual tax on practitioners, which is palpably unfair without a far larger direct representation; by increasing the sum now paid for admission to the *Medical Register*, which is already sufficiently high at five pounds; or, last but not least, by rendering registration compulsory. The establishment of a Students' Register would not only solve the financial difficulty, but would also give the Council authority in a direction where authority is sometimes needed. At the last Session but one, a resolution in favour of asking the Lord President of the Privy Council to introduce a Bill into Parliament

to confer this power on the Council was passed by a majority of twenty-two to six—a mandate quite strong enough for the purpose if it had been allowed to stand. What has been the sequel? No sooner had the Council stated a clear and definite opinion than the Royal College of Physicians and Surgeons of England approached the Lord President by correspondence, protesting against that opinion as an infringement of their rights, and the Lord President in consequence wrote to the Council suggesting that a conference between the Council and the Colleges should take place, so that existing rights might be safeguarded. This letter formed the subject of the debate which resulted in the Council passing a motion to the effect that a reply should be sent to the Lord President saying that the opposition of the Colleges was too strong, and that the Council would prepare an alternative scheme at its leisure. In a word, the Council has caved in completely, and practically acknowledged themselves beaten by the Colleges, not in fair and square debate in the Council Chamber, but by outside tactics. If this is the way that the Council is to be treated, one may well despair of the future. As Sir Victor Horsley—the strongest and clearest-headed man on the Council—pointed out, the Council was appointed by Act of Parliament to be supreme arbiter in matters of medical education, and that position should be recognised by the Privy Council. The licensing bodies are represented in overpowering numbers on the Council, and have every opportunity of making their views known in debate. To suggest a conference is manifestly out of place, as the Council itself is the official conference for matters of this kind: the opinion of the Council embodies the opinion of all the licensing corporations—after full discussion. This the Privy Council does not seem to understand; at all events they treat the Colleges which appeal to them as though they were entitled to be considered on equal terms with the Council. It is a lamentable spectacle for the general practitioner to see the Council, through which alone hope of reform can come, flouted and set at naught by the close corporations which are bent on preserving their privileges. The maintenance of the dignity of the Council and the extension of its authority, together with increased representation on it of the body of the profession, are objects that vitally concern the welfare of the public and the medical man.

### Notes on Current Topics.

#### Preventive Treatment of Cancer.

THERE are few surgeons of wider experience than the Bradshaw Lecturer of this year, Mr. Mayo Robson. It is to be expected, therefore, that the views he has put forward on "pre-cancerous conditions" (a) will attract a good deal of attention. He is of opinion that the onset of malignant disease is preceded by one or other of a

(a) THE MEDICAL PRESS AND CIRCULAR, December 7th.

number of conditions whose presence should suggest the adoption of preventive measures. If this be true, and if these pre-cancerous conditions be capable of recognition, then a great step in the prevention of malignant disease will have been taken. Mr. Robson states in detail several of these conditions, which he regards as leading to cancer. For instance, cancer of the mouth often follows on a chronic ulcer, syphilitic, tuberculous, or dental in origin, or on the irritation caused by tobacco smoke. An old ulcer of the stomach may give rise to carcinoma, eczema of the nipple to malignant disease of the breast, gall-stones to that of the gall-bladder. That all such conditions should be treated is Mr. Robson's opinion, and most of them by the use of the knife. When we ask, however, what is the common feature in which these very varied conditions agree, we are at a loss. In fact, as far as we can see, there is nothing in common but that they give rise to long-continued irritation, and it has been believed by many thinkers that irritation conduces to the growth of malignant disease. But we can hardly think that Mr. Robson suggests that all the conditions he mentions lead inevitably to cancer, or that every seat of irritation is to be removed by the knife. But unless he means this, we are still in the dark as to which of the "pre-cancerous conditions" are to be so treated, and which are not.

#### A Crime of Devotion.

A MURDER of exceptional medico-legal interest took place recently at Droitwich, but we were unable to comment upon it at the time as the murderess was arrested promptly, and our remarks had consequently to be held over till the prisoner had been tried. An old lady, Mrs. Tabitha Lawson, living at Droitwich, had had the prisoner, Mary Holdaway, in her service for forty-seven years, and the two old people—for at the time of her mistress' death Mary Holdaway was sixty years of age—were exceedingly fond of each other. Mrs. Lawson fell ill with some chronic malady that caused her continual suffering, and through her long illness she was tended with slavish devotion and self-sacrifice by her old servant. There can be no doubt about the facts, for in his evidence Dr. Bryceson, Mrs. Lawson's son-in-law, said he had never seen such unselfish devotion as Mary Holdaway showed her mistress. One day, while temporarily alone with her in the house, Mary Holdaway cut her mistress' throat. Dr. Bryceson happened to arrive shortly after, and Mary opened the door, and, clinging to him like a frightened child, kept repeating in a whimpering voice, "Whatever made me do it?" There was no doubt that she was the culprit, and there was no concealment of the facts. Neither was there any motive in the ordinary sense of the word. Counsel for the defence put to the jury the theory that Mary's mind was constantly preyed upon by Mrs. Lawson's suffering, and that her intense love for her mistress goaded her to commit the crime. This the jury accepted, and the poor woman was

mercifully found to be insane at the time of the murder, and therefore not responsible for her actions. Although love has not infrequently acted indirectly as a motive for murder, we do not remember an instance in which it has taken the line it did in this case. The story reads more like the creation of a realistic novelist than one of sober fact, but it must certainly be added to the long list of medico-legal romances that are stranger than fiction.

#### "Grafts."

A COUPLE of years ago there was a good deal of discussion in the American and home journals on the question of the legitimacy of what was called the "division" of the consultant's fee. It was the custom, not, we are glad to say, in this country, for the consultant to return a portion of the fee to the practitioner who had called him in. The good sense of the profession, both here and in America, condemned the practice as being highly objectionable, if for no other reason than that it introduced in the selection of a consultant considerations other than the interest of the patient. Nevertheless, the system has persisted in America, and we learn from our Transatlantic contemporaries that it is by no means unusual for the practitioner to demand a "graft," as it is called, from a particular consultant, in consideration of recommending him. In some cases, indeed, the "graft" is by far the major portion of the fee paid by the patient. For instance, *American Medicine* relates the story of a surgeon who agreed to perform a certain operation for a sum of five hundred dollars. Some time later he learnt that the patient had actually paid two thousand, of which the practitioner had pocketed the balance. We learn from our contemporary that customs such as this are not contrary to business morality in the States, but we trust it may be long before they are accepted by either professional or business men in this country.

#### Bob Sawyer—Ad Nauseam.

ADMIRERS of Dickens—and we are old-fashioned enough to include ourselves among them—are fond of insisting that with all his humour and all his pathos, he was one of the greatest moral influences of the middle of the nineteenth century. No other writer, not even excepting Charles Reade, did more to rouse the public conscience, while entertaining the public intellect; and this great end he was able to accomplish without offending susceptibilities or spoiling a good picture by using too warm a brush. The reason, we take it, was that Dickens was a caricaturist in the truest sense of the word—one, that is, who points his characters with a subtle grace and humour. Just as Mr. Chamberlain is said to be one of Mr. F. C. Gould's warmest admirers, so the medical profession feel that they have no grudge against Dickens for his delineation of Bob Sawyer and his pranks. But there are people, without much humour, we fancy, who out-Dickens Dickens, and find in that clever caricature the eternal type of the medical student. On behalf

of the medical profession we beg to say that we are rather tired of them. In a divorce case tried last week the co-respondent was a medical student of Italian parentage. We have no comments to offer on the merits of the case, which resulted in the jury being unable to agree upon a verdict; but we do protest against the fact of the co-respondent being a medical student being used by the counsel for the husband as an argument in favour of guilt, or, at least, a presumptive element of prejudice. Counsel is reported to have said that the co-respondent was not a child; he was studying for a profession in which wild oats were supposed to be freely sown during student days, to be atoned for by exceptional severity of life afterwards. A speech of this kind is as derogatory to the profession from which it emanated, as its intention was to that at which it was levelled. The study of medicine is at least as ennobling as that of the law, and perhaps it is in consequence of this fact that we ourselves should decline to cast unworthy flouts at future officers of the Courts of Justice.

#### Ethical Pharmacy.

THE prescribing chemist and the patent drug dealer in this country cause sufficient vexation to the medical man who has high ideals as to the methods by which relief should be conveyed to suffering humanity, but surely he would lose his vexation in amusement if they really manage these things in America in the manner described by Dr. Benedict, of Buffalo. From an entertaining paper by him in *American Medicine* (November 26th, 1904), we learn that the city drug-store represents a *bizarre* combination of businesses. It is usually a public telephone office, a branch post-office, express office, place to pay gas bills, sometimes a branch circulating library, and laundry. One can buy candy, hair-brushes, tooth-brushes, soap, valentines, knives, tobacco, soda-water, "soft drinks," and occasional strong drinks. At some stores the attractions include a light lunch, pet animals, and gold-fish. In the midst of what Miss Squeers would call this "delightful embarrassment," there is displayed a notice indicating the *raison d'être* of the establishment in such terms as "prescription counter in the rear," or "prescriptions a speciality." As Dr. Benedict suggests, such a proceeding is about as consistent as if a medical man were to announce that he made a speciality of attending patients. But the competing attractions of the store pale before the whirl of entertainments provided by the shop-windows. Life-size cards remind passers-by of the virtues of plasters "which feel good on the back," and serve partially to hide the charms of ladies and gentlemen in undress. Gigantic green frogs amuse children and call attention to remedies for frog-in-the-throat at the same time, whilst a paste-board trained nurse can be made to advertise nearly anything, and if she can do some automatic feats with a sprinkler or atomiser, she is doubly charming. We rather gather that

there is some difficulty in making one's way to the prescription counter through this hive of industries, especially as to do so one has to pass a series of cures for every disease, neatly done up with directions for use and priced at a cheaper rate than the prescription is dispensed at. In order that the directions may not make too great a tax on the intelligence of the sufferer, they are printed in pamphlets containing information on astronomy, a collection of popular songs, or a complete joke-book. Life for a chemist in America may be busy; it should certainly not be dull.

#### The Dangers of Ice.

A RATHER unseasonable contribution to public health literature is Sir Shirley Murphy's just published report to the London County Council on the way in which the ice-trade is carried on in London. We need hardly say that the report reaches the high standard of interesting thoroughness that we are accustomed to associate with Sir Shirley Murphy's work, but nevertheless it sends cold shivers down the back in more ways than one. At the present season ice as an addition to one's food and drink does not suggest the same comforting ideas that it does in July and August, and we are inclined to think that unless some action is taken on the report even the dog-days will seem more endurable without ice than with it. It is frequently thought that the freezing of water renders it innocuous as regards bacteria, but not only is this not the case, but it has been shown that spores survive even the most intense degrees of cold that can be obtained by means of liquid air. Ice, therefore, unless made from pure water of unimpeachable antecedents, is just as potent and an even more insidious foe than water in its ordinary fluid condition. Apart altogether from the source of the water from which ice is derived, and seeing the facilities that now exist for making artificial ice, Sir Shirley Murphy suggests that all ice for mixing with food and drink should be made from distilled water—there is, to say the least, room for great improvement in the way that ice for internal consumption is handled by dealers. It is hardly unreasonable to insist that ice that is to be put in drinks or placed in contact with fish and butter should be transported in some more cleanly way than the usual one of being wrapped up in filthy bits of sacking in open carts, whence it is often thrown out on a pestilential city pavement.

#### Congenital Word-deafness.

A CURIOUS symptom in the course of certain cerebral diseases is the condition described by Kussmaul as "word-deafness." In this condition patients are unable to understand the meaning of spoken words, even though the hearing itself be uninjured. The occurrence of the symptom is definitely associated with lesion of the posterior part of the first temporal convolution on the left side, and is consequently most often found along with deafness of the right ear. The recorded cases of acquired sensory aphasia of this sort are,

of course, very numerous, but we do not remember previously reading of any case where the condition was congenital. Dr. Syme, of Glasgow, has, however, recently met with a child who apparently had been born word-deaf. He is quite intelligent in other respects, hears sound fairly well, and is able to imitate the sounds made by animals. But he has no idea of the meaning of words, for although he can repeat easy words which are spoken to him, they are never connected with objects in his memory. When first brought under observation hearing was a little dull, but both hearing and speech have been improved by careful training. Dr. Syme is inclined to account for the condition as being due to a faulty development of the centre in the left temporal convolution.

#### The Secret of Secret Remedies.

It is an experience of all of us to have to attend a patient who has been under a course of treatment by some secret cure. He may present a drug rash or some other symptom of chronic poisoning as a result of the treatment, and it is important under such circumstances to have some knowledge of the nature of the drug under whose influence he is. The number of secret medicines, patented and otherwise, in common use is so large that it is impossible for the practitioner to cumber his mind with details regarding all of them. Of the most common it is advisable, however, that every medical man should know something, and such information is notoriously hard to get. In a lecture delivered twelve months ago at the London Hospital, Dr. Robert Hutchison gave many particulars with regard to several of these remedies, naming, as far as possible, the ingredients present in each. One of our contemporaries is starting a series of articles on the subject, and in a recent number (*a*) gives analyses, quantitative as well as qualitative, on the composition of some of the best-advertised cures for epilepsy. It is satisfactory, in a way, to note that none of those examined is likely to be dangerous in itself, since they contain no other drug than those commonly ordered for the disease. The basis of nearly all is one or other of the bromides, the dose in some cases, however, being larger than it is advisable to use without medical supervision. A great contrast is noticed, however, between the price of the preparation and the estimated cost of the drugs used. Two cures which have a large sale at 2s. 9d. and 3s. per bottle respectively are calculated to cost each about one penny per bottle. There is truly no limit to the gullibility of the public.

#### Dogs in Warfare.

CONSIDERING the almost human intelligence of the dog, it has often been a matter of wonder that more use has not been made of him in warfare. That he can be employed for purposes requiring extraordinary intelligence was shown long ago by the monks of St. Bernard, who trained the dogs of that monastery to rescue unfortunate

travellers lost in the snow. Various modern armies have made use of dogs for the special purpose of carrying aid to the wounded, as well as for fulfilling the ordinary functions of sentinels. In the present war in the East the Russians are making use of large numbers of dogs for these purposes. It will be remembered, too, that at the time of the expedition of the allied troops to Peking, much interest was aroused with regard to the dogs attached to the German army. The Germans, indeed, seem to have devoted more attention than any other nation to the subject, and at the annual trainings the Medical Staff Corps are provided with dogs for ambulance purposes. In America, Italy, and other countries dogs are similarly employed. In our own country Major Richardson has for many years endeavoured to persuade the War Office of the advantages to be gained by a proper use of canine help, but so far without success. This year, indeed, having devoted much time and pains to the training of ambulance dogs, he was at length invited to demonstrate his methods in the autumn manœuvres. As a result, General Sir Charles Tucker has recommended the use of dogs trained by Major Richardson's method to the War Office, but as yet no reply has been given. The special utility of the dog is, we believe, in aiding the stretcher-bearers by discovering wounded on the field of battle.

#### "Professor" Alex and the London Hospital.

A HYPNOTIST has recently appeared in London under the title of "Professor" Alex. One newspaper contained a grave account of how he paralysed healthy persons, a phenomenon of suggestion well known to medical science. It has also been scientifically recognised that certain forms of functional paralysis may be made to vanish from a patient under the influence of a strong will. The curable "paralysis," however, must be functional and not organic, that is, it must be due to a mere suspension of healthy nerve action and not to structural changes in brain and nerves. In other words, it is only the, so to speak, mind-created paralysis that can be cured. When, therefore, curiosity-seekers flock to see the palsied made whole, it is well to remind them that the wonders are worked upon defective minds rather than upon the bricks and mortar of our fleshly tabernacle. "Professor" Alex, it need hardly be remarked, is not a qualified medical man. He has stepped over the fence in stating that he has cured "cases which had been discharged as incurable from the London Hospital." His assertion was promptly challenged, but the promise from the "Professor" to correct his mistake from the stage was not fulfilled. The Chairman of the London Hospital, the Hon. Sydney Holland, thereupon wrote to the newspapers denying that any one of the "Professor's" so-called "patients" had ever been in the "London." It is shameful enough that a quack of his kind should be allowed to prey on the public, apart from bolstering up his false pretences by brazen untruths; but after all, there is

(\*) *Brit. Med. Journ.*, December 10th, 1904.

little to choose between one quack and another. The public are being fleeced, damaged and killed on all hands by kindred roguery of the worst possible type. The inherent cruelty and wickedness of the "backache" pill may be taken as an instance. When pain in the back is due to kidney mischief nothing can avert dangerous or fatal results except prompt and skilled medical care. Yet the shameless quack proposes to cure the kidney trouble by nostrums sold at a hundred times their actual value. The humane medical man can only shake his head and murmur a prayer for the poor wretches who are thus deceived. The responsible party is, in reality, the Government which endorses each box of pills for the sake of a paltry stamp fee, and abstains from passing laws to shorten the tether of the quack medicine vendor who sucks the life-blood of the community.

#### Plum-Pudding from all Points of View.

THE part played by plum-pudding in the formation of the national character can hardly be grasped, even in the land of its birth, save by the highest and rarest types of intellect. Its wonder-working charm begins in the nursery, it is continued in the schools, and carried out thence into the busy walks of grown-up life. In all the seven ages of man—not to mention women and babies—it cheers, sustains, comforts, nourishes, soothes, and eke fascinates. Who but an Englishman, born and bred to its toothsome winsomeness, could tell how the essence of plum-pudding has entered into and mellowed and ripened and buttressed the very marrow of his bones? Years ago we wrote of the nutritious virtues condensed in that "speckled globe of savoury delights." Since then base rivals in medical journalism have analysed the atoms of this glorious and hallowed dish with crucibles and test-tubes, and have announced to an indifferent world its precise amount of nutrient matter measured in calorics and what-not scientific jargon. Away with that kind of cold-blooded science! Let the Englishman live for to-day and for ever, happy in the unscientific enjoyment of his plum-pudding. Let us be thankful that in this year of our Lord, although bread and flour and sugar be dearer, yet raisins and currants, on the other hand, be cheaper, while suet and strong ale and brandy and the rest of the dear old classic ingredients, have gone neither up nor down. Let us say, modestly but firmly, of our pudding, *Semper eadem—floreat semper.*

#### Personal Hygiene in Soldiers.

THE alleged physical deterioration of recruits has been supposed to be due to several causes which, reacting unfavourably upon the growth and development of the infant, succeeds in lowering the standard of health in the adult. Many of these—such as overcrowding, mal-nutrition, and parental intemperance—act in combination; and in the preparation of statistics it is difficult to say with precision which factor is the particular predisposing one in any given case. Presuming that

the recruit is of average physique, it is, of course, of supreme importance that he should know how to preserve his body in the highest state of efficiency, both in times of peace and when engaged in active service. The knowledge of hygienic matters possessed by the average "Tommy" is, however, surprisingly small, as Lieut-Colonel H. K. Allport has pointed out in a recent issue of the *Journal of the Royal Army Medical Corps.* The ignorance of the men themselves with regard to such simple matters as the care of the teeth, the prevention of foot-sores, and the need for fresh air and regular washing is only too general, and were it possible to disseminate elementary instruction of this nature more widely a great deal of unnecessary suffering and physical inefficiency might be prevented. The suggestion is put forward that the officers of the Royal Army Medical Corps who possess the necessary training should undertake the task of teaching the men, and if such instruction takes the form of practical demonstrations it is generally much appreciated. Example is better than precept, but without the latter the former often fails to produce the desired impression. Efforts in this direction, as carried out with the Royal West Kent Regiment at Maidstone, were eminently successful in the instruction taking the form of popular lectures in the gymnasium upon elementary physiology and hygiene as applied to the every-day life of the soldier.

#### Signs of Drunkenness.

A MEDICAL practitioner is reported to have stated in Court that "there were no definite signs of drunkenness to guide a medical man." Such an assertion is, of course, perfectly true, for there is not a single symptom of acute or chronic alcoholism, with the possible exception of Quinquaud's sign, that may not occur equally in other morbid conditions. This is a little unfortunate from the point of view of the man in the street, who believes implicitly in the doctrine of "one disease, one sign." Were such universally the case the science and art of medicine would consist of little else beyond a committal to memory of a list of diseases with their corresponding infallible signs. The minds of some of us cannot help reverting to this analogy when we turn over the leaves of some of the excellent medical diaries supplied to each member of the profession by certain enterprising firms. Good as these productions are, we do not desire to see them degenerate into a medical rival of Mrs. Beeton. The diagnosis of alcoholism is some times easy and at others extremely difficult, involving, as it does, a full knowledge of every morbid condition leading to excitement, coma or muscular inco-ordination. The fact that alcohol, in some shape or other, is frequently administered by the friends of a patient in fits or unconsciousness due to nervous or arterial affections further helps to complicate matters. Poisoning by other drugs, and, above all, the possibility of injury to the head with or without visible tokens, have also to be borne in mind. There is no one cardinal sign of drunkenness any more than there is one particular

sign indicative of heart-disease. It is the appearance of a certain "symptom-complex" or group of clinical manifestations alone upon which the diagnosis of alcoholism is based, and he who trusts to one sign only will surely be deceived in this as in every other departure from the normal state.

#### Doyen's Work in Cancer.

THE researches of Dr. Doyen have been considerably discounted among the medical profession in Great Britain owing to the curious secrecy which he has maintained as to methods and details. After the recent action, however, brought against him by an American, whose wife had died under treatment by his serum, Dr. Doyen asked for a responsible medical investigation. That step was taken by the formation of a committee, including Professor Metchnikoff of the Pasteur Institute. Five chief questions are said to have been considered: (1) Does the microbe discovered by Dr. Doyen (the bacillus *neoformans*) exist? (2) If so, is it undoubtedly the cancer microbe? (3) Is it unmistakably distinguishable from other known microbes? (4) Can Dr. Doyen's microbe form the basis for a serum to be used in inoculation? (5) Does Dr. Doyen's serum cure cancer? So far as we can gather the Committee find that the bacillus mentioned was found present in all the cancerous tumours examined, and that the serum has always produced favourable results when administered in inoperable cases. It need hardly be pointed out to medical readers that these statements, assuming their authenticity, are of potential rather than of actual value. It may be that Doyen has succeeded where other investigators have failed—or, again, it may not be the case. Some day the great discovery will undoubtedly come, and the name of another great modern benefactor be added to the roll of fame.

#### A Public Vaccinator as Magistrate.

AS an orthodox medical journal, no one could for a single moment suspect the MEDICAL PRESS AND CIRCULAR of undue sympathy with the anti-vaccination cult. At the same time, anti-vaccinators have their legal rights just as much—no less and no more—than their saner fellow-citizens. If there be one thing more desirable than another in the interests of scientific preventive medicine, it is that the vaccination laws should be administered in such a way as to avoid the least breath of a suspicion of unfairness. It seems eminently undesirable, therefore, that a public vaccinator of a district should be called upon to adjudicate on vaccination cases as a local magistrate. Last week it was reported that Dr. R. R. Brown, of Strood, one of two justices at the Rochester Police Court, directed an order to be made out for the vaccination of a child within fourteen days. The defendant thereupon pointed out that Dr. Brown was favourably interested as the public vaccinator for Strood. The defendant further submitted that the information was bad and the summons irregular. Whatever the ultimate outcome of this case

may be it is obvious that public vaccinators who happen to be magistrates would act wisely in retiring from the bench when vaccination cases come before the Court.

#### PERSONAL.

THE Secretary of the North Wales University College announces that the recent bequest to the college by the late Dr. Isaac Roberts is expected to realise £15,000.

DR. ROBERT WM. BOYCE, Holt Professor of Pathology in the University of Liverpool, sailed from the Mersey on Wednesday last, accompanied by Dr. Evans and Dr. Clarke, as the thirteenth expedition under the auspices of the Liverpool School of Tropical Medicine to the West Coast of Africa. A considerable number of friends, including Professors Ronald Ross and Williams, and the popular hon. secretary, Mr. Alan Milne, assembled on the landing-stage and gave the voyagers a hearty send-off.

DR. HENRY JELLETT has been appointed to the post of Obstetric Physician to Dr. Steeven's Hospital, Dublin, to fill the vacancy caused by the death of Dr. J. L. Lane. The posts of Gynæcologist and of Obstetric Physician have thus been amalgamated.

DR. R. J. ROWLETTE has been appointed Pathologist to Dr. Steeven's Hospital, Dublin.

THE *London Gazette* for December 13th contains the names of four Army surgeons "mentioned in despatches" relating to the Tibet Expedition. Among these the highest in rank is Lieutenant-Colonel L. A. Waddell, C.I.E., I.M.S., a former student of Glasgow University, where he qualified as M.B. and C.M. with honours in 1878, and was made LL.D. in 1885.

ANOTHER surgeon thus distinguished is Major A. R. Aldridge, R.A.M.C., who graduated in 1885 as M.B., C.M., of Edinburgh University, and took the English Conjoint D.P.H. in 1892.

THE third Army surgeon to be honoured is Major C. N. C. Wemberley, I.M.S., also a graduate of Edinburgh University, where he took the M.B., C.M., in 1889.

THE fourth gentleman mentioned is Captain T. B. Kelly, I.M.S., who is F.R.C.S. Edin. (1895) and Licentiate of the Scotch Colleges of Edinburgh and Glasgow. He was educated at Queen's College, Galway, where he was at one time Demonstrator and Assistant Lecturer on Anatomy.

THE Inaugural Dinner of the Association of Medical Diplomates of Scotland will be held in London near the end of January. Particulars may be obtained from the Hon. Sec. David Walsh, M.D., 18A Hanover Street, London, W.

THE retirement of Dr. Trollope is announced from the physiciancy to the Hastings Hospital, a post which he has held for no less a period than thirty-nine years.

AT a meeting of the Court of the University of Edinburgh on December 12th, Principal Sir William Turner announced that, in reply to an appeal to friends of the University for funds to purchase a site for other educational buildings, and for extension of the teaching staff Sir Donald Currie had intimated a subscription of £25,000.

THE Liverpool School of Veterinary Medicine and Surgery was opened on December 13th, by Mr. Walter Long, President of the Local Government Board, who spoke of the importance of this department of study

from the point of view of the physical welfare of the nation, and said that Liverpool was the first university of the country to open its arms to veterinary students.

The next ordinary meeting of the Royal Meteorological Society will be held at the London Institution of Civil Engineers, on Wednesday, December 21st, at 7.30 p.m., when the discussion will be taken on Mr. F. J. Brodie's paper, "Decrease of Fog in London during Recent Years."

LORD RAYLEIGH, we understand, intends to present to the University of Cambridge the amount of the Nobel prize for Physics, which has just been awarded to him.

The Right Hon. Joseph Chamberlain, M.P., will preside at a banquet in London on May 10th next on behalf of the London School of Tropical Medicine.

It is announced that the University of London Unionist Association has invited Sir Philip Magnus to contest the Parliamentary representation of the University at the next Election, and that Sir Philip has consented to stand. The sitting member is Sir Michael Foster, M.D., F.R.S.

A MEETING will be held in the Town Hall, Manchester, on Thursday, January 19th, 1905, at 4 p.m., for the purpose of establishing an institution to promote the social and scientific unity of the medical profession. It is stated that numerous promises of support have been already received. Members of the medical profession are invited to be present at the meeting.

### Special Correspondence.

[FROM OUR OWN CORRESPONDENTS.]

#### BELFAST.

THE OLD ROYAL HOSPITAL.—Since the opening of the new Royal Victoria Hospital last year, the old hospital in Frederick Street has been for sale, and various proposals for its use have been made. The Belfast Guardians now propose to acquire it for a temporary additional workhouse, and at their last meeting it was announced that the Local Government Board had given their consent to the arrangement, provided it can be shown that the premises are suitable for the purpose. The building would provide accommodation for about 400 persons, and it is to be feared that a good deal of additional accommodation will be required during the winter, beyond what the workhouse normally affords. Like all other manufacturing towns, Belfast is at present suffering from bad times and lack of employment for the working classes, though it is hoped that the new electric tramway system construction, which is to be begun at once, will afford employment for a large number of labourers.

THE POLLUTION OF BELFAST LOUGH.—For as long as the oldest inhabitant can remember there have been complaints every summer and autumn of the smell from the slob-land at the head of the Lough, and the warmer the weather the warmer the language used by the oldest inhabitant. Since the present drainage system was introduced the nuisance has become much worse, and an inquiry into its cause made by Professor Letts showed that it was due to the masses of decaying seaweed of the species *Ulva latissima*, which flourishes in the sewage-polluted water. At the instance of one of the rural councils of the neighbourhood another inquiry was held this week, this time by Mr. P. C. Cowan, chief engineering inspector of the Local Government Board. The inquiry seems to be an exceedingly futile one, for it is perfectly well known that the weed grows in sewage water, and that the smaller towns and villages on the shore of the Lough all add their quota to the pollution, in proportion to their population, though, of course, Belfast is the most generous contributor. The only result of the inquiry will probably be a profusion of promises of amendment.

#### EDINBURGH.

EDINBURGH UNIVERSITY IMPROVEMENT FUND.—At the meeting of the University court on the 12th inst., Principal Sir William Turner was in the fortunate position of being able to announce that in response to the appeal made for funds in aid of University improvement, a sum of £40,000 had been promised. Of this sum, £25,000 has been given by Sir Donald Currie, who in his letter intimating the donation, said that he wished the revenue from the sum to be applied to the remuneration of a staff of lecturers such as the University authorities might from time to time appoint, but that, if they found it necessary to do so, the University Court might apply £5,000 of the amount towards the purchase of a site for new laboratories. Sir Donald Currie's desire was to assist in placing the metropolitan University of his native land on a sound financial basis, and at the same time to aid one of the objects of the Carnegie Trust. He had communicated with the Chairman of the Trust, asking that, in view of his gift, the £10,000 voted by the Trust as a capital sum for the endowment of teaching should be paid as soon as possible to the University, or that its income should be made available from the beginning of session 1905-6, and that a further contribution should subsequently be made to University improvement. The chairman of the Executive Committee of the Trust, Lord Elgin, has expressed his sympathy with the object to which Sir Donald Currie's gift is to be applied, and promises to bring the whole matter before the Trustees.

THE REMODELLED LEITH HOSPITAL.—Within the last month the improvements in this hospital, which were begun in 1898 by the building of a new wing to the surgical block, have been completed, with the result that the institution, which has now been almost entirely remodelled, will bear favourable comparison with any other hospital of its size in the kingdom. The last addition has been the erection of a surgical out-patient department replete with every convenience, including a small theatre. A very complete electrical installation has also been put in, including the most recent appliances for high-frequency work. The hospital is an old building, standing in the most crowded part of one of the poorest districts in the city; up till comparatively recent years, all kinds of cases—fever, medical, and surgical—were treated within its walls. To have remodelled, and practically rebuilt the institution so as to convert it into a modern hospital with accommodation on the most approved lines for medical, surgical, and gynaecological cases, including as that did the construction of a nurses' home, the building of new laundries, and a complete reorganization of the working of the institution without having even for a day interrupted the routine of its daily work, was a task of no little difficulty, but now that it has been accomplished it is only just to say that no small part of the credit is due to the indefatigable secretary, Mr. G. V. Mann, whose work for the good of the hospital during a long period of years makes the institution his debtor to an extent which is to be reckoned, not in pounds, shillings, and pence, but in the position which, thanks so largely to him, the hospital now occupies in the estimation of the community.

#### GLASGOW.

THE TREATMENT OF NEURASTHENIA.—At the fortnightly meeting of the Glasgow Southern Medical Society held on Thursday, last, Dr. Thos. K. Munro, Professor of Practice of Medicine in St. Mungo's College, read a paper on this subject. He related some cases to illustrate typical forms of the disease, describing in detail the various forms of the disease—acquired and traumatic—including cerebral, spinal, gastric, and cardiovascular. He considered it was comparatively easy to distinguish between genuine cases of this disease and those of malingering. The prognosis in neurasthenic cases was generally hopeful where the circumstances of the patient allowed of the proper line of treatment being carried out. Dr. Munro advocated the adoption of some hobby by such patients; an outdoor one for

those who were previously closely confined, and sufficient exercise, falling] short of fatigue, at all times. Drs. Carstairs Douglas, Macgilvray, Stewart, Hight, Weir, Halliday, and the President, Dr. James Hamilton, took part in the discussion which followed. Reference was made to the treatment of neurasthenia by means of the high-frequency current. It was recognised that in some cases this modern and fashionable mode of treatment did good. The Weir-Mitchell treatment had, of course, many advocates, but its cost restricted its use to those patients who were in easy circumstances. On the motion of the President, a hearty vote of thanks was awarded Dr. Munro for his interesting paper.

**PROSECUTION UNDER THE FOOD AND DRUGS ACT.**—A medical man in Glasgow, keeping an open surgery with shop on the south side of the river, was last week fined £4, including expenses, in the Summary Sheriff's Court, for selling three ounces of spiritus ætheris nitrosi, which was deficient in ethyl nitrite to the extent of 38 per cent. or thereby. The defence was that the drug was highly volatile, and difficult, to keep, each time the stopper was removed from the stock bottle a certain amount of depreciation took place. It was sold as it was got from the wholesale house. The prosecutor said there was no suggestion of fraudulent intent on the part of the respondent, the whole case being that the medicine had not been properly kept. This action does appear rather harsh of application, and shows that the Pharmaceutical Society is still active, and as this prosecution took place against a medical man with a shop open for the retailing of drugs, we may venture to say that there is great insecurity for others who may be similarly situated. There are certainly many dispensing and retailing spiritus ætheris nitrosi to whom it would never occur to test it, in order to prove that it was of the required or standard strength.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our Correspondents.]

#### THE LAY PRESS AND THE PROFESSION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—My attention has been called to the appearance in several lay papers of some observations of mine on "temper powders," as if they had been written for the lay Press. As a matter of fact, these are quotations from a paper "On the Use of Salicylate of Sodium and Bromide of Potassium in the Irritable Temper of Cardiac Disease and Gout." This paper appeared in *The Practitioner* of July, 1896, and parts of it having been quoted by one paper without acknowledgment of its source, they were reprinted by other papers. Hence my remarks, intended solely for medical readers, have been supposed to be written for the general public. I regret this very deeply, for I think that had I done this, as many believe that I have, I should have been guilty of conduct derogatory to the profession to which I belong, and naturally am much grieved that I should be supposed to be guilty of this. I regret also that the quotations may do actual harm to health, because the drugs mentioned, though perfectly safe in the hands of the medical practitioner, for whom the paper was written, may prove mischievous in the hands of persons ignorant of their properties.

I am, Sir, yours truly,

LAUDER BRUNTON.

10 Stratford Place, Cavendish Square.

[We sympathise with the annoyance Sir Lauder Brunton has experienced owing to the vagaries of modern journalism. If we remember aright, one of these journalists had the unparalleled audacity to translate the *Practitioner* into the form of a personal interview with Sir Lauder.—Ed.]

#### HOSPITAL FUNDS AND SMALL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Sewill makes one think of the Heathen Chinese, so child-like and bland. I wonder if he really

means us to believe that every candidate for every appointment at every hospital does not make use of every scrap of influence he has at his command. I would not go the length of saying that every appointment goes by influence, but I have no hesitation in saying that influence helps. It would be ridiculous to believe otherwise.

It is doubtless true that some of the work done at some of the special hospitals is bad, but the same may be said of some of the general hospitals, where, to my own knowledge, the most ordinary surgical principles seem to be completely ignored. Mr. Sewill's advice to abolish most of the special hospitals looks as if he wished to crush out all opposition. He seems to forget that the special hospitals have led, and that the general hospitals have followed. Live and let live is not a bad motto.

As I do not require a hospital appointment, my interest is only that of

Yours faithfully,  
OUTSIDER.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I am sure you are right in your main contention about the hospital funds. Intelligent interest in the administration and application of the funds cannot be taken by donors or would-be donors, for the simple reason that the information supplied by the Committees under these heads is meagre in the extreme. It should be the aim of these Committees to let the public share all the information that they acquire in their official capacity, and to report fully on their inspections of the various hospitals, when, as in the case of the King's Fund, these are made by authorised visitors. The mischief caused to the funds of withholding such information I can illustrate from my own experience. I had recently under my care a wealthy gentleman, widely known for his donations to philanthropic institutions. He consulted me one day with regard to subscribing to the King Edward VII Fund, the particulars and official publications of which he had carefully studied. I told him all I knew of the work of the Funds, but he was not satisfied. A keen man of business, he informed me that he never gives away a penny unless he is sure that the administration of the financial arrangements of a charity is of the strictest and soundest, as he has often been scandalised by the light-hearted way in which debts are incurred by eleemosynary institutions. Now this gentleman, after a careful study of all available documents, decided that a very handsome sum which he was prepared to subscribe ought to be withheld, as he could not assure himself that it would be used to the best possible advantage. I confess that I felt unable to disagree with him.

I am, Sir, yours truly,

LONDINIENSIS.

December 15th, 1904.

### Literary Notes and Gossip.

THE German Universities provided a very valuable educational exhibition at this year's World's Fair at St. Louis, and the Committee of the Medical Exhibit, of which Professor Waldeyer was President, issued an excellent handbook (German Educational Exhibition, St. Louis: Medicine. Berlin: W. Büxenstein, 1904), which strikingly indicates the energy and scientific enterprise of our German *confreres*, and is well worthy of study by English teachers of medicine.

THE current number of *Tuberculosis*, the official publication of the Central International Bureau for the Prevention of Consumption (Leipzig: J. A. Barth) very appropriately is devoted to the memory of M. Finsen. Among the illustrations is one which admirably portrays our King and Queen at the Finsen Institute.

EGYPT is deservedly a popular land for the health and pleasure seeker, and Assouan has won distinction as one

of its most attractive and advantageous health resorts. Mr. G. Dundas Edwards M.R.C.S. in his "Notes on Assouan," (London: John Bale, Sons and Danielsson), furnishes much practical and trustworthy information regarding meteorological conditions and climatic states which medical men may well study before advising a case to journey to the Land of the Pharaohs. The suggestions regarding the regulation of food, dress, and exercise are judicious, and the section on sun and sand baths contains useful precautions.

\*\*\*

The *Polyclinic* for December contains a lengthy article by Sir Alfred Fripp on the "Radical Cure of Internal Derangement of the Knee-joint."

\*\*\*

DR. DABBS has given us much that is rich in dramatic force and has contributed largely to poetic prose, but throughout his writing there is ever marked the keen clinical instinct of the physician and abundant evidence of the alert mind of the analysing psychologist, mingled with the sympathies of the naturalist and a fellowship born and bred in loving contact with suffering humanity. In his latest essay into the region of romance, "A Sparrow, a Mouse, and a Man: A Study in Solitude" (London: Partridge and Cooper), we have a study of primitive methods as applied in "solitary confinement," and although there is a touch of the whimsical in the story, many points of considerable psychological importance are enforced, and for those willing to read between the lines important practical conclusions will not be hidden.

\*\*\*

THE January issue of "Longman's Magazine" will contain the opening chapters of two new serial stories. The first of which will especially interest the medical profession, as it is written in collaboration by Walter Herries Pollock and his son, Guy C. Pollock, and is entitled "Hay Fever." It is concerned with the adventures of a much and justly respected stockbroker, and is founded on the known action of a drug sometimes prescribed for hay fever; but, naturally, the authors have aimed more at amusement than at scientific accuracy.

\*\*\*

"Who's Who," for 1905, has just been issued from the press by Messrs. A. and C. Black, and is, as its title implies, a biographical record in alphabetical order of personages more or less distinguished from Royalty downwards to the plain Mr. Smith, who is supposed to be endeavouring, or to have endeavoured, to make the world a little better than he found it, when, *mirabile dictu*, without the asking, he was cast on its shores to fight his own little way in his own little time. Of course, in a compilation of this nature some arbitrary rule must necessarily be adopted regarding admission to its pages. Here and there may be found the names of medical men, whilst many are omitted who not unnaturally might consider themselves more eminent. The book is, moreover, not without amusement, we have just lighted on a celebrity thus described: "twice married, now a widower, educated by his mother," etc.

\*\*\*

THE Scientific Press announce that they will shortly publish an "Elementary Treatise on the Light Treatment for Nurses," by Dr. James H. Sequeira, Physician in Charge of the Skin Department at the London Hospital.

\*\*\*

THE ninth edition of Dr. Macnaughton-Jones's "Manual of Diseases of Women," has just been issued by Messrs. Bailliere, Tindall and Cox. In its revised form it is the most beautifully illustrated work on the subject with which we are acquainted, and is *bound* for the first time in one volume or in two, as preferred by the purchaser. We hope to review it shortly.

### Obituary.

DR. ROBERT B. MOORE.

DR. ROBERT B. MOORE, of Rockcorry, co. Monaghan, died on the 12th inst. at the advanced age of 82. Dr. Moore was a native of Rockcorry, and practised there

as dispensary officer for many years. He enjoyed a large and extensive practice, and was looked on by one and all as a very able practitioner. His remains were interred in the family vault at Kilcrow on the 15th, many people attending the funeral from all parts of the surrounding country.

### AN IMPROVED STETHOSCOPE.

MESSRS. SUMNER AND Co., of Liverpool, have forwarded a specimen of a portable stethoscope of an exceedingly workmanlike and efficient pattern. We have tested this instrument carefully, and find it one of the best all-round stethoscopes that we have hitherto seen. The chest-piece has a celluloid diaphragm whereby the sounds are collected and transmitted from the drum to both ears. The whole packs away neatly into a leather purse of reasonably small size, and it is carefully constructed in every detail. One would think the last word had been said about stethoscopes, and that the practitioner had only to choose between the old-fashioned transmitting tube and the modern applied principle of the microphone. Messrs. Sumner's stethoscope, however, shows that there may be excellent half-way houses. The extremely moderate price, a few shillings only, brings it within the reach of all. Students will find this stethoscope excellent for ward purposes.

### Medical News.

National Association for the Prevention of Tuberculosis.

THE fourth annual meeting of the Dublin Branch of the National Association for the Prevention of Tuberculosis was held on Wednesday last at the Royal College of Physicians. The Lord Mayor presided.

Dr. Alfred E. Boyd, Hon. Secretary, read the annual report, which showed that the total number of deaths caused by tuberculosis in its many forms in Ireland during 1903 was 12,180, representing a rate of 2.8 per 1,000, whilst in 1902 the rate was 2.7. Of the 12,180 deaths, consumption was responsible for 9,559, corresponding to a rate of 2.2 per 1,000 of the population. Of these deaths, 4,667 were of males and 4,892 were of females. Of the males who died from consumption during the year, 64 per cent., and of the females 58 per cent., were between the ages of 20 and 45 years. During 1903 tuberculosis caused more than twice as many deaths as were caused by influenza, epidemic diarrhoea, whooping cough, measles, typhoid, and diphtheria together. In the face of these figures, the fact was deplored that the methods by which the death-rate from this cause is being lowered in other lands are still so imperfectly understood and adopted at home. The adoption of the system of voluntary notification of consumption has, on the whole, been productive of but little benefit. The Sheffield Corporation has obtained the sanction of Parliament to a provision which makes notification of consumption compulsory, and the Rathmines Urban Council are now taking a similar step, the result of which will be watched with interest. Both Cork and Belfast have shown much activity with respect to the establishment of sanatoriums for the consumptive poor, but in Dublin matters remained as they were a year ago, and the difficulty of dealing with cases in tenement houses is as great as ever. It was much regretted that the Dublin Corporation have again deferred the appointment of a City Bacteriologist.

Dr. W. J. Smyly proposed, and the Lord Mayor seconded, the adoption of the report. A resolution urging upon sanitary authorities the necessity for making consumption a notifiable disease was then proposed by Mr. Thomas Edmundson, and seconded by Dr. E. J. McWeeney. The officers for the ensuing year were then elected and the proceedings terminated.

## Notices to Correspondents, Short Letters, &c.

**✉** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive Signature or Initial*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland, to the Dublin office, in order to save time in re-forwarding from office to office. When sending subscriptions the same rule applies as to office, these should be addressed to the Publisher.

REPRINTS.—Reprints of articles appearing in this journal can be had at a reduced rate providing authors give notice to the publisher or printer before the type has been distributed. This should be done when returning proofs.

M.R.C.S.—Our correspondent, in our opinion, having acted in strict accord with ethical procedure, has nothing to reproach himself with.

M.D. (Salisbury).—From the layman's point of view, there was perhaps some justification for describing the late physician named, as an "Eccentric Doctor."

### OUT-PATIENTS AND HOSPITAL LETTERS.

On the first page of each letter is printed in large type, "Keep this paper clean." This office is usually entrusted to the baby, when it tires of hokey-pokey and other refreshments supplied in the waiting-room by sympathetic mothers described as "kind ladies." Another plan is to fold the letter into as small a compass as possible and hold it tightly in a greasy palm, or else to wrap it in the family pocket handkerchief. It is mostly lost when wanted, and the search for it entails a prodigious rummage into pockets, bags, and reticules, during which the doctor fumes and grumbles. Finally it will be triumphantly produced from beneath the baby's under-petticoats.—"Our Hospitals and Charities Illustrated."

BEATUM FULMEN.—Do not engage in any further correspondence, which will be fruitless; but submit the case forthwith to the Medical Defence Union, of which we gather you are a member.

### THE DOCTOR WHO SAVED HIS LIFE.

"One day in Shanghai, when I was feeling sick," says a recent writer on the Yellow people. "I called a Chinaman to me and said, 'John, do you have good doctors in China?' 'Good doctors!' he exclaimed. 'China have best doctors in world!' 'Eudon, do there,' I said, pointing to a house covered with a doctor's signs—'do you call him a good doctor?' 'Eudon good doctor!' he exclaimed. 'He great! He best doctor in China! He save my life once!' 'You don't say so!' I said. 'How was it?' 'Me velly sick,' he said confidentially. 'Me calleo Doctor Han Kou; givee some medicine; get velly, velly sick! Me call Doctor Sam Sing; givee more medicine; me grow worse. Going to die! Bimeby call Doctor Eudon; he no got time, no come. He savee my life!'"

W. WESTERN.—The rumour, as we have definitely ascertained, is without foundation.

AMICUS.—The next vacancy on the Surgical staff will probably occur in two years time—at the hospital in question.

### MEDICINE IN TONS.

Sir Frederick Treves at the Mansion House, London, recently said that in the London Hospital alone they used in the course of a year:

- 1,000,000 pills.
- 3 tons of Epsom salts.
- 3 tons of carbolic acid.
- 14 tons of ether and chloroform
- 10 tons of lint.
- 8 tons of cotton-wool.

While 700 kangaroos supplied ligaments for tendons. In one year, he added, there were 14,384 operations, or forty a day.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY DECEMBER 21st.

ROYAL MICROSCOPICAL SOCIETY (30 Hanover Square, W.).—8 p.m. Paper: Mr. J. W. Gordon: The Theory of Highly Magnified Images.

ROYAL METEOROLOGICAL SOCIETY (Institution of Civil Engineers, Great George Street, Westminster, S.W.).—7.30 p.m. Discussion on Mr. F. J. Bredie's paper on Decrease of Fog in London during Recent Years. Paper: Mr. W. N. Shaw and Mr. W. H. Dines: The Study of the Minor Fluctuations of Atmospheric Pressure.

### Vacancies.

Nottingham General Hospital.—Assistant House Physician. Salary

£100 per annum, with board, lodging, and washing in the Hospital. Applications to the Secretary.

Nottingham General Hospital.—Assistant House Surgeon. Salary £100 per annum, with board, lodging, and washing in the Hospital. Applications to the Secretary.

King Edward VII. Sanatorium.—Medical Superintendent. Salary £500 per annum, with board, lodging and attendance. Applications to the Secretaries, 19, Devonshire Street, Portland Place, London, W.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer.—Salary £130 per annum, with board, lodging, and washing. Applications to the Medical Superintendent.

New Zealand.—Professor of Physiology at the University of Otago. Salary £800 per annum, with half of the Class Fees. Applications to the Agent-General for New Zealand, 13 Victoria Street, London S.W.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Dorset County Hospital, Dorchester.—House Surgeon. Salary £100 per annum. Applications to W. E. Groves, Valetta, Icenway, Dorchester.

North Staffordshire Infirmary and Eye Hospital, Hartshill, Stok-upon-Trent.—House Surgeon. Salary £110 per annum, with furnished apartments, board, and washing. Applications to the Secretary.

Colliery Club.—Resident Surgeon. Salary £200 per annum. Applications to A. J. Godfrey, Secretary, Vernon Road, Kirby-Ashfield, near Nottingham.

Guildford Borough.—Medical Officer of Health. Salary £100 per annum. Applications to F. S. Miller, Town Clerk's Office, Guildford.

Waterford County and City Infirmary.—Resident House Surgeon. Salary £100 per annum, with board, &c. Immediate application to Cecil J. Wyatt, Secretary. (See Advt.)

## Appointments.

BRAND, ARTHUR MATHER, L.R.C.P. Lond., M.B.C.S., Medical Officer and Public Vaccinator for the North District and Workhouse of the Stratton (Cornwall) Union.

BYRNE, J. P., L.R.C.S., L.R.C.P.I., appointed Senior Resident Surgeon, Provincial Hospital, Port Elizabeth, Cape Colony.

CARR, FRANCIS JOHN HUGHES, M.B. Lond., L.R.C.P., M.R.C.S., Medical Officer to the Dawlish (Devon) Lodge of Oddfellows.

ENGLISH, T. CRISP, B.S. Lond., F.R.C.S., Assistant Surgeon to St. George's Hospital; Lecturer on Operative Surgery, St. George's Hospital Medical School, London.

GAGE, D. P., L.R.C.P. Edin., L.F.P.S. Glasg., D.P.H., Certifying Surgeon under the Factory Act for the Kilmanning (Barth) District of the county of Ayr.

GEE, C. A., M.R.C.S., L.R.C.P., Medical Officer for the No. 7 District by the Shepton Mallett (Somerset) Board of Guardians.

HOYER, W. T., M.D. Canada, Clinical Assistant to the Chelsea Hospital for Women.

LESLIE, ROBERT, W. D., L.R.C.S. & P.I., Resident Medical Officer to the Royal Hospital for Incurables, Donnybrook, Dublin.

RYAN, J. B., L.R.C.P. & S. Irel., Certifying Surgeon under the Factory Act for the Taghmon District of the county of Wexford.

SHEPPARD, J. F., L.R.C.P. & S. Irel., Certifying Surgeon under the Factory Act for the Newport Pagnell District of the county of Buckingham.

## Births.

CAMPBELL.—On December 16th, at 28 North Street, Elgin, the wife of Donald Graham Campbell, M.B., O.M. Edin., of a son.

EASTON.—On December 15th, at 92 Brigstock Road, Thomas Heath, the wife of Harold Augustus Easton, M.R.C.S., L.R.C.P., of a son.

## Marriages.

FOXGROFT—COCKBAIN.—On December 15th, at Christ Church, Sebo Park, Liverpool, Frederick Walter Foxcroft, M.D., C.K. Birmingham, younger son of the late Joseph Foxcroft, Cheetham Hill, Manchester, to Mary Lydia, daughter of the late Thomas Cockbain, Liverpool and Valparaiso.

GRIFFITH BULLMORE.—On December 12th, at Penwarris Church Falmouth, Cornwall, Gordon E. Griffith, of the Colonial Civil Service, West Africa, to Susan Ethel Bullmore, younger daughter of the late Charles Forrester Bullmore, M.R.C.S., L.R.C.P., L.M. Lond., of Helston, and of Mrs. Bullmore, of 11 Stratton Terrace, Falmouth.

## Deaths.

ALLARD.—On December 11th, at 1 Rodney Terrace, Cheltenham Arthur William, eldest son the late Dr. Wm. Allard of Tewkesbury, aged 53.

LOCKE.—On December 6th, at Cawdor House, Botherham, Charles Alfred Locke, M.R.S., L.R.C.P., younger son of John Locke, late of Barbados, aged 40.

SEDGWICK.—On December 14th, at the London Hospital, E. suddenly Norah Emma, daughter of W. Sedgwick, M.R.O.S., of 75 King Edward's Gardens, Acton, W.

TUNMER.—On December 13th, after a long illness, at Leinster Lodge, Fulham Road, London, James Robert Tunmer, M.R.C.S., aged 78.

### ON THE VALUE OF THE OFFICIAL REPORTS ON INSANITY.

By W. R. MacDERMOTT, M.B., T.C.D., F.R.C.S.,  
Medical Officer of Poynts Pass District.

THE reader of the comments in the lay press on the official reports of the Commissioners in Lunacy and of the superintendents of the asylums must note in the writers a feeling of bewilderment often ending in naïve expressions of doubt and distrust. The feeling is not at all confined to the lay mind. When medical men, not necessarily in the light of their own technical knowledge, read a few of these reports—for the sake of their own mental stability they should not read too many of them—they cannot but understand and share in the perplexity of the lay reader.

This is apparent even when we take what is more peculiarly within the province of the medical man, the treatment of the insane individual in view of the incidence of the disease. Following Herr Schlagenhausen, Dr. Godsell, Arnold White, and others, though with characteristic moderation, Dr. Rentoul proposes to meet the disease by the sterilisation of *certain* degenerates, with respect to which I must say that, as a medical man, I would kick hard against the onus of having to determine in practice that "*certain*" being thrown on me. On the other hand, medical men too numerous for citation advocate the boarding out or "home" treatment of degenerates—"certain" degenerates, of course—oblivious of the fact that association-intercourse with the insane, is a well-recognised cause of insanity.

It would be unfair to expect in a wide field of observation, and from a body of observers with varying personal equations and limits of study, a uniform statement of fact. In the field of observation of insanity, phenomena or facts, strikingly apparent in one part, are obscure or absent in another, and it is the duty of the individual observer to record the facts within his personal knowledge, but without a knowledge of the whole field he cannot safely generalise from the partial data at his command. A physician in attendance on typhoid cases in a hospital is able to accumulate valuable information as to the disease, but he would be a very acute man indeed if he could from such data give an account of the causation of it in palaces and hovels, cities and countrysides. In the same way the able superintendents of our asylums accumulate valuable information as to the patients in their charge, but their range of observation is not the actual field of incidence of the disease, and therefore we need not look to them for an adequate account of its causation, or even of its general incidence. They give us what we have a right to expect from them. They are hospital physicians—I need not say rather strictly so. They give us what they have to give—experience formed in their hospitals. It would be well if they

told us that they knew little or nothing as to the disease in the country, or as to the circumstances and conditions under which it occurred outside the asylums in their charge.

It would be well if they would tell the Commissioners in Lunacy, Commissions of Inquiry of their several kinds, the Medico-Psychological Association of Great Britain, and all others appealing to them for information, what the information they can give is really worth, and thus enhance the service they render the community, a service of all others the most arduous, difficult, and disagreeable.

They would, indeed, preserve their dignity and efficiency in that position and escape much unfavourable criticism by realising the exact tenor of the requests for information they receive. They will find on reverting to the circulars they have received from time to time from the Commissioners in Lunacy, and to their answers to these circulars, that a competence in them to decide certain questions is assumed which, on reflection, they would not assume themselves. Thus in the Special Report of the Commissioners in Lunacy to the Lord Chancellor (February, 1897), the Commissioners state that they commenced their inquiry by addressing a circular letter to the superintendents of all the county and borough asylums in England and Wales, "asking their views on the subject of the alleged increase of insanity occurring out of proportion to the increase of population in the districts represented by their several institutions, and requesting those of them who were of opinion that such increase had taken place to specify in detail the facts and figures upon which that opinion was based, and the apparent causes of such increase."

Replies were received from 62 superintendents and others, of which 10 were of opinion that relative increase had occurred, 30 that it had not, and 22 declined to give any opinion. Now if the 62 men had a single spokesman he would have said that the general answer was perfectly correct and perfectly worthless, since if relative increase had occurred, it would be a mean quantity the resultant in sum of increasing, decreasing, and stationary terms. He would say that a change of state affecting a minute fraction of population could not be supposed to be uniform over the country, that the answers received correctly indicated that fact, but were worthless as giving an adequate representation of it.

Not even the Commissioners give the superintendents credit for stating collectively the proper answer to a meaningless question. They say: "In some instances it will be seen that no very clear distinction has been drawn between the increase of insane persons, as to which there can be no dispute, and an actual increase of insanity disproportionate to that of population, respecting which there is a wide difference of opinion." Even without this remark the popular mind after its nature would attribute looseness of thinking and want of knowledge to the 62 superintendents, collectively and individually. What it wants itself it naturally takes as wanting generally.

The want of knowledge and looseness of thought are

altogether on the side of those making the inquiry. A superintendent of an asylum is able to say whether the number of insane persons in his charge is increased or otherwise, but he will not infer from increase a general relative increase all over the country or even, as a permanent fact, a relative increase in the district his asylum serves. If the number of cases of typhoid in a hospital doubled, the physician would not infer a general relative increase of the disease all over the country, and any inference he would make as to local incidence would need data apart from the number of cases treated in hospital. The superintendent of an asylum is perfectly justified in merely stating an increase of insane persons in his charge and expressing any opinion he likes for what it is worth as to the cause of the increase. His expression of opinion is no part of his statement of fact, and should not be considered as such.

All these official inquisitions into the prevalence of insanity have the same character. They all go to the asylums and to their superintendents "as scientific experts whose special attention had almost necessarily been fixed on the subject."

The superintendents, and, in general, medical men engaged in the treatment of insanity, however, while scientific experts as regards the pathology and treatment of the disease are not, and would not claim to be, experts as regards facts altogether outside of their range of observation, and which they have no occasion to deal with, or even to consider. If, at the instance of the Commissioners in Lunacy, they express opinions about what they have not considered, these opinions will be taken to mean not inability to form a judgment, but, from their conflicting and contradictory character, as pretension to a knowledge they do not possess.

To understand the false position in which they are placed and the use to which they have been put, they should remember that it has been publicly stated that the authorities do not want any *bona fide* inquiry as to the prevalence of insanity, or any discussion on the subject. It has been stated (*Fortnightly Review*, January, 1893) that the lunacy reports, *i.e.*, the information our superintendents were at the pains to compile, had for years been delayed until Parliament had risen, so that the opportunity of calling attention to them on the Estimates could not arise. Again, the Commissioners in Lunacy in the three kingdoms have been charged with using the argument implied in the phrase, "apparent increase of insanity," in no *bona fide* sense as an argument, but to evade inquiry. I am not here speaking for the superintendents of the asylums, but, as far as I can judge, they cannot be held collectively responsible for the implied argument, now ridden to death. If, however, they have any reason to think that their reports have been, to put it mildly, misunderstood in the past, they may take it as a reason to be on their guard in the future. Here, for instance, is the latest proposal coming from official quarters for an inquiry into the "causes" of increase of insanity in Ireland. The Inter-departmental Committee on Physical Degeneration recommends:—

"That an investigation should be undertaken at an early date into the extent and character of the increase of lunacy in Ireland, and a serious effort made to trace it to causes which might be the subject of some ameliorative interference."

In any such investigation the superintendents of the asylums would, of course, as heretofore, be called on to take a prominent if not exclusive part, with the result that a report would be concocted which would be a *fac-simile* of those already in existence. The report professedly based on the evidence of the superintendents would represent the views of probably not a single one of them, and be as valueless or valuable as its predecessors. The reason is on the surface of the proposal. The logic of causation demands that sequence or change of circumstance shall be traced within integral limits, *i.e.*, the entire limits within which the circumstances can be determined. Insanity in Ireland is no unitary fact, and taking it as such necessarily involves gross fallacy. Thus Irish insanity is ascribed to emigration under the crude supposition that

it drains away the "bone and sinew" of the country. This gross fallacy is, of course, to be corrected by extending the area of inquiry to the United States, and the British colonies, when it will be found that the Irish abroad are as much if not more affected than those at home. Again, in the *British Medical Journal* (October 22nd, 1904), it is stated that "the chief cause of the growth of insanity in Ireland seems to be simply decadence." The Irish population is predominantly rural or agrarian, and if we read agrarian instead of Irish, we will find that in England the agrarian element of population is as "decadent" and as much affected by insanity as in Ireland, the only difference being that the element is relatively a small one. Real inquiry would need this observation to be extended over the agrarian element in Western Europe and in general to all populations having the same form as the Irish and undergoing the same change of state. If the superintendents of the Irish asylums admit that such should be the area of inquiry they should not allow their own narrow local experience to be made the basis of a report which would show them up at loggerheads among themselves.

The limitation of inquiry to "causes which might be the subject of some ameliorative interference" would put the superintendents in a position even more absurd than the limitation of inquiry into a general phenomenon to a particular small area. Of course, the intention is to exclude conventional morality and certain social forms as causes of insanity on the ground that it is useless to touch them. If, however, the old notion that lunacy was due to the moon's state or to an astronomical cause was true, the knowledge of it would enable us to avoid assigning false causes and trying useless remedies for the disease. The diagnosis of disease or its etiology aims at cure and prevention, but is not governed by that aim; as scientific men we are bound to determine causes or antecedents free of pre-conception, and from the mere utilitarian point of view to exclude false causes and *prima facie* notions.

The reports of the superintendents of the asylums can have no value if they are conformed to instructions which violate the canons of scientific evidence, or, in other words, the rules of common sense. I venture to suggest to the superintendents to give their reports in future value by conforming to these rules and refraining from answering inquiries which contradict them.

I may enforce this suggestion by stating the manner in which, as I conceive, an effective investigation into the incidence of insanity must be conducted, which is the manner in which I have myself conducted investigation in, of course, a limited field of observation.

In the first place, what is to be sought is mere description of where and among whom it occurs, its distributional maxima and minima. The causation, or so-called causation of the disease, which is generally hypothesis of effect, should wait on this.

The occurrence of the disease is, as a first step, to be identified in place and time. This can only be effectively done by taking maps of districts and marking houses as representing families contributing cases of the disease within a given period, or by forming an inventory of all the families in the districts and ascertaining the number contributing. As numerical data only are needed, this could be done without violation of private life, but under any circumstances it is not merely childish but criminal in a matter of such importance not to take the only efficient means of determining the actual facts, the only means of getting rid of the dense clouds of falsehood in which the subject is enveloped by men who will not learn, and can never be brought to learn, the nature of *prima facie* ideas.

The value of this method of investigation can be seen at once by comparing, say, the Shankill road district in Belfast with a rural area of equal population in Tyrone or Armagh. In the first-named area there are dozens of public houses, and the population, a working class one, is in a visibly unsatisfactory state, social, moral, and sanitary. In the rural district, wherever taken, there need be no public house, and there is no immorality, illegitimacy, or prostitution, no social misery

and degradation; judged by the death-rate, the sanitary state is very good, and everyone goes regularly to church, chapel, or meeting. Now the man who goes by his *primâ facie* notions would say off-hand that the Belfast district would give the maximum, the rural the minimum, of contributory families. But from personal observation and statistics I believe the Belfast district would be found to give about 10 per cent., and the rural 50 per cent. It has to be noted in addition that the rural group is a pure or unmixed one, while the urban is largely composed of an immigrant rural element.

The method of investigation thus indicated in outline is applicable not only to circumstances of place and time, but to individuals, in whatever way they may be grouped, and thus gives the true logical form for inquiry. The table of causes of insanity of the Medico-Psychological Association is a mere fallacy-trap for our "scientific experts." Thus alcoholism as a "cause" of insanity is not a cause in any true sense, but simply an observation of how many of the insane are found to be under the alcoholic habit. No number, however large, would establish causal relation or an effect. The whole group of persons under the habit gives  $x$  lunatics, but for all we know the numerical value of  $x$  may be less than  $y$ , the figure for the general population, or than  $z$ , the figure for a group not using alcohol at all. I believe  $x$  would be found much less than either  $y$  or  $z$ , not because alcohol prevents insanity, but because the alcoholic habit is a characteristic of a class socially distinct from the group of families giving the maximum of insanity.

In the same way syphilis cannot be proved from numerical data collected in the insane group to be either a cause or effect in insanity. The number of insane in the syphilitic group may, for all we know, be less than the number in any equal non-syphilitic group of the same age-period. This again is due to class distinction; the group of rural families giving the maximum of insanity are almost entirely free from syphilis in Ireland.

Suppose ourselves able to identify anywhere a group of families with specific character and found it increasing, would we be reasonable in stating influences of a destructive nature operating on it as the cause of its increase? Identifying the group contributing to insanity in proportion as we would find it under the influence of alcoholism and syphilis, we would have a cause for its decrease, not for its increase. If destructive agencies do operate, it is by disadvantaging in a higher degree on balance the non-contributory group and so leaving the field to the group predisposed to insanity. In the *Edinburgh Medical Journal* (September, 1903), and elsewhere, I have pointed out that the last-named group is a clearly marked historical one, and is increasing in Ireland and all similar agrarian areas by virtue of the biological law of selection. The group has and had an advantage in its own area and is accordingly increasing. I need not repeat myself here. What is to the point, however, is that as long as I went by the official reports of Commissioners in Lunacy and of superintendents of asylums, I found nothing, in myself, at least, but confusion of mind; not until I consulted the concrete field of observation did I get a gleam of light on the subject. The reports want value because going on worthless *primâ facie* notions of causation and ignoring the whole biological field and the laws operating in it as a whole, applicable therefore to insanity as a partial circumstance in it. Until they take insanity in its environment and under the law of its environment they can reflect little credit on their compilers.

PLYMOUTH BOARD OF GUARDIANS.—At a meeting of the Plymouth board of guardians held on November 23rd, it was decided that a new infirmary should be erected on the site occupied by the garden adjoining the workhouse.

## NOTES ON THE GENERAL MEDICAL COUNCIL AND ITS PROCEEDINGS.

By GEORGE JACKSON, F.R.C.S.Eng..

Direct Representative on the General Medical Council.

As one of the direct representatives of the medical profession for England and Wales, I wish to bring under the notice of my constituents some of the salient points of the matters which have been discussed in the Council at its recent meetings, more especially with reference to the meeting held in November of this year. It may be within the memory of those who have taken an interest in the proceedings of the Council, that there has been a long-standing dispute between the

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS  
OF ENGLAND AND THE COUNCIL,

as to what should be recognised as a sufficient preliminary scientific examination. A report on these examinations was presented to the Council in May, 1903, but the consideration of it was deferred on account of the gravity of it, to a special meeting held in July of the same year. The report was made by Mr. J. Campbell Brown and Dr. Windle. With reference to the first year's examination of the English Conjoint Board, they reported that the standard of the examination was a low one. "The physics portion of the examination amounts to nothing, while the chemistry portion does not afford any assurance that knowledge has been acquired of such a kind as will fit a student to commence the study of physiology, and enable him to understand his reading and acquire a wider knowledge in after life. The syllabus, the details of the paper, the plan of the first and principal part of the practical examination, are at fault, and especially the absence of any guarantee of sufficient preparation for the examinations." The remarks on the examinations of the Apothecaries' Hall, London, and the Scottish Conjoint Board were not so unfavourable, but the standard in each case was considered too low, as was also the case with regard to the Irish Conjoint Board examination, although this examination on the whole was perhaps the best. Resolutions were passed at the July meeting that in the opinion of the Council both the examinations and courses of study recognised by the Royal Colleges of England were insufficient, and the examination of the Apothecaries' Hall was insufficient. In consequence of the representations made to the examining bodies, the syllabuses and the examinations have been very much improved. It is, however, much to be regretted that the English Colleges still recognise as places of study, institutions which are not suitable in the opinion of the Council. It is important that the teachers should be themselves well qualified, that the laboratories should be well equipped, and that the work should be done in the daytime, not at night, as the mental faculties of the students will probably be exhausted by other studies and work during the day.

### REGISTRATION OF STUDENTS.

It is well known that owing to the multiplying work of the Council, the increasing number of the members of the Council, and owing to the greater number of Universities entitled to send representatives to the Council, and to the diminishing number of registrations, the financial condition of the Council is not in a satisfactory state. In

order to remedy this, various proposals have been made from time to time, with the approval of the Privy Council, and a proposition was made and carried by a large majority at the May meeting of the Council, to the effect that a short Bill should be introduced into the Houses of Parliament to make registration by the Council compulsory by students, and that a fee of £1 should be paid by the student.

Unfortunately, at the November meeting of this year exception was taken to this course, and it was evident that the Bill would be opposed in Parliament by the representatives of various corporations, more especially by those of the Royal Colleges of England—those bodies objecting to the Council having the power to register students, and by inference to lay down the conditions of registration. The result was that the Council reversed its resolution of May last and finally resolved to send a reply to the Privy Council—*viz.*, that owing to the opposition by certain licensing bodies, the Council does not desire to ask the Lord President to introduce the measure formerly proposed into Parliament. Personally, I did not agree with this resolution, and voted against it, as did the other direct representatives for England. In my opinion, it would tend to the unification of the system of medical education if one body had the control of the registration of students and their courses of study.

With regard to the financial part of the question, I have always favoured a small annual licensing fee. I moved a resolution in favour of this some sessions ago, but it did not meet with much support. It would have supplied the Council with sufficient funds to carry out its work properly; it would also have brought every practising medical man in touch with the Council, so that if his conduct had not been satisfactory in the past it might be inquired into.

#### MEDICAL PUPILAGE.

At the commencement of the recent meeting of the Council I asked the President to define what was the exact meaning to be attached to the phrase—"The proper training and instruction of *bonâ fide* medical students as pupils"—occurring in the notice regarding the employment of unqualified persons as assistants or otherwise, issued on November 24th, 1897. The President replied in effect that it referred to the fifth year of the curriculum, six months of which may be passed as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as shall be satisfactory to the medical authorities. The reason of my asking the question was that it has come to my knowledge that unqualified assistants are employed in numerous cases, more especially in the colliery districts in the North of England, under the guise of pupilage. I ascertained that the Conjoint Board of the Royal Colleges of England does not recognise any such pupilage, and that the English Apothecaries' Hall has had no application for such recognition. It cannot, however, be too widely known that the General Medical Council cannot institute any prosecution in such a case; but that the case must be brought before them by some person or body of persons, such as one of the Medical Defence Unions. It, therefore, now rests with the persons who are acquainted with such cases to take action in the matter. I am informed that medical men generally are not acquainted with the resolution

of the Council referring to the matter, so that it is possible that many are acting in ignorance of it.

With reference to the desirability of reviving in some form and to some extent the old system of pupilage, Mr. Geo. Brown, one of my colleagues as a direct representative on the Council, moved a resolution with reference to it which I seconded, the purpose of it being that students who had served one year's pupilage with a practitioner—who could satisfy the medical authorities that he could give sufficient opportunities of imparting practical knowledge—should be exempted from six months' clinical work at a public hospital. Both Mr. George Brown and myself promised when we were candidates for election as direct representatives on the Council that we would urge this matter on the Council. Unfortunately, it met with little support, Dr. Bruce, the direct representative for Scotland, alone supporting it, in addition to ourselves. The remarks I made on the matter have been partially misunderstood. I did not intend to say that the medical student as a pupil would be taught the art of treating the patient instead of always treating the disease. I wished to convey the idea that the student should be taught the art of treating patient *as well as* the disease, and that he would be more likely to learn that from an experienced medical practitioner than in the wards or out-patient departments of hospitals. I very well remember the late Mr. Arthur Durham sketching out what he thought would be an ideal student's career, and including in it twelve months with a general practitioner, who had large opportunities for seeing practice.

#### FINAL EXAMINATIONS OF THE SCOTCH UNIVERSITIES.

There was an animated discussion on this report, especially on the part referring to the practical part of the examination in surgery at the University of Edinburgh, when it appears that operations on the cadaver are not required from every candidate, but only from those selected, I believe, by ballot, so that it is only fair to say that any candidate may be required to operate. This part of the examination was considered unsatisfactory by the inspector and visitor, who appeared to think that this part of the examining process is usually unsatisfactory, except at Glasgow, where they expressed great satisfaction with it. There is no doubt of the necessity for it, seeing the advances that surgery has made of recent years, and how impossible it is to acquire the requisite dexterity without sufficient practice on the cadaver. It is somewhat noticeable that none of the Scotch universities, except St. Andrews, lay much stress in their examinations on knowledge of diseases of eye, ear, throat, nose and skin, but at this University there was an elaborate examination in these diseases—well arranged, and on all points satisfactory. In the end it was decided that there should be a re-inspection of the final surgical examination of the University of Edinburgh. There is no doubt but that this University suffers from a plethora of students, and in consequence a lack of teaching material.

#### MEDICAL COMPANIES BILL.

This is a matter of extreme interest to the medical profession at large. It arises, as is well known, from the fact that seven persons can combine and form a company and do that which it is unlawful for one man to do. This practice has

received a check by the judgment of Chief Baron Palles, in Ireland, by which the Registrar was interdicted from registering a company, but, as Sir Charles Ball remarked, a company may go on for ever, and therefore it is necessary to deal with the companies already registered. An attempt in that direction is being made in Ireland, but the matter is at present *sub judice*. The Council has communicated with the Lord President of the Privy Council on the matter, expressing the hope that the Government will take such steps as may be necessary to prevent the provisions of the Medical and Dental Acts being evaded by persons improperly taking advantage of the provisions of the Company Acts.

The penal business of the Council does not appear to call for any especial comment, substantial justice being done in each case.

### French Clinical Lectures.

## PERIODIC PARALYSIS OF HEREDITARY ORIGIN.

By DR. L. CHEINISSE,

Late House Physician to the Montpellier Hospital.

[SPECIALLY TRANSLATED FOR THE MEDICAL PRESS AND CIRCULAR.]

SOME twenty years ago Professor Westphal published "A Remarkable Case of Periodic Paralysis of the Four Limbs Associated with Disappearance of Electrical Excitability." Discarding the possibility of its being of malarial origin, the author described the case as probably unique, although a Russian observer, three years before, had brought forward a case of "Intermittent Nervous Spinal Paraplegia" closely resembling that of Professor Westphal's. In Dr. Chakhnovitch's case, the motor disturbances appeared and disappeared during the night, leaving merely an ephemeral numbness of the extremities. It is worthy of note that the father of this patient appears to have been similarly afflicted in childhood and succumbed to an attack of the kind at the age of 54. On comparing the symptoms in the two cases it is obvious that they are similar, but Westphal's description gives greater prominence to one of the most remarkable features of periodic paralysis, *viz.*, the complete loss of electrical excitability without any trace of degeneration in the paralysed muscles during the persistence of the paralysis. Although periodic paralysis is a rare affection, it is something more than a pathological curiosity. The literature of the last twenty years contains a certain number of cases which suffice to show that it is a morbid entity with well-defined clinical manifestations. In its typical form the attack is characterised by the onset of paralysis with diminution or complete loss of electrical excitability and of the reflexes, without any concomitant sensory or intellectual disturbances. In contrast with paralysis of malarial origin the recurrence of the attacks is governed by no law of periodicity: sometimes they occur daily, in other instances the attacks are separated by a longer interval. In a case recorded by Dr. Goldflam, the attacks occurred once or twice a week in summer and every two months in winter. There may apparently be a single attack, as in the mother of Goldflam's first patient, who had her first and only attack at the age of 36. As a general rule the attacks are occasional at the onset, increasing in frequency later on, and after persisting at a high level for many years they begin to diminish in frequency. The duration of the attacks varies, not only in different individuals, but even in the same person. Usually lasting several hours, they may persist for days or may subside in a quarter of an hour.

The paralysis often supervenes during sleep, the patient, on awakening, discovering that he is unable to move. When it supervenes in the waking subject

it is ushered in by sundry preliminary phenomena such as weakness in the limbs, a sensation of fatigue, drowsiness, pricking, formication, intense thirst, &c. According to Dr. Cousot, the attack is not always complete from the onset. The patient may be engaged in copying and the paralysis only attacks the unoccupied limbs, the active limbs only being affected when work is relinquished. A sharp walk may, in the same way, delay the extension of the paralysis to the legs. Speaking generally, repose is as favourable to its development as active exercise is contrary thereto. The influence of immobility in favouring the onset of the paralysis has been clearly described by Goldflam, who was able to induce an incomplete attack of paralysis of all four limbs, with loss of electrical excitability, &c., merely by keeping the patient for some time in the sitting posture. Some authors, however, have observed attacks following great physical fatigue, but even in these cases the paralysis only supervened after a period of repose.

Even if incomplete at the onset the paralysis rapidly extends. As far as one can judge it usually commences in the lower limbs, thence extending to the trunk and upper limbs, but in some instances it began in the arms or hands. In one case the paroxysm was precipitated by the prolonged pressure of the hands on the handles of a bicycle.

It is but rarely limited to the lower limbs, and, as a rule, the paralysis involves all four limbs and the muscles of the trunk. When it invades the respiratory muscles the patient complains of a difficulty in sneezing and coughing. Occasionally the muscles of the neck are also involved, interfering with the head movements. It but rarely happens that the lingual and pharyngeal muscles are affected, although Westphal and Cousot both observed disturbances of swallowing and speech. In a case recorded by Dr. E. W. Taylor, the motor branch of the fifth nerve was slightly affected during severe attacks, but usually—and this is one of the distinctive characters of the malady—the cranial nerves are unaffected. Even when all the voluntary muscular system participates in the attack, the movements of the eyes and facial muscles remain intact. The unstriated muscles also appear to escape invasion, and the constipation observed in some instances was probably due to loss of the action on the part of the "abdominal compressors" rather than to any paresis of the intestinal muscles. Dr. Taylor, it is true, notes complete absence of micturition in one case during the attack, although this lasted thirty-six hours, but he admits that it could not be described as retention, but was due rather to the absence of any desire to water, dependent, partly, on reduced renal activity, and possibly also the patient's difficulty in moving himself.

The severity of the paralysis varies within wide limits, the motor disturbance amounting to anything from mere paresis to absolute paralysis. Speaking generally it is less pronounced in the upper than in the lower half of the body.

One of the most distinctive and important features of this form of paralysis consists in the temporary abolition of faradic and galvanic excitability, in a degree corresponding to the severity of the attack. This affects the nerves as well as the muscles. This symptom, as Westphal remarks, is "unique of its kind," for it is never met with in any other disease of the spinal cord or of the spinal nerves, and it had been observed in every case of periodic paralysis in which the electrical test has been applied. When the muscles are completely paralysed, not the slightest contraction can be obtained, no matter how powerful the current; in less marked cases the excitability is diminished *pro tanto*. In the course of an attack certain groups of muscles may still react to the electrical stimulus, while others are absolutely indifferent thereto. Dr. Goldflam notes that the idio-muscular excitability, like the electrical excitability, diminishes in proportion to the severity of the attack, and may, similarly, be totally abolished.

The deep reflexes are almost always diminished or

abolished during the attack, but the superficial reflexes are less constantly affected. These disturbances, indeed, depend merely upon the distribution and the intensity of the paralytic phenomena. Since the lower limbs are almost invariably more markedly affected than the rest of the body, it is easy to understand that the patellar reflex is wanting in most instances, and that the abolition of the plantar reflex is more frequently observed than that of other cutaneous reflexes.

The paralysis is usually flaccid, with complete resolution, but Chakhnovitch and Greidenberg have noted a certain degree of contraction in particular muscle groups. The extent and the severity of the motor disturbances present a striking contrast with the absolute integrity of the special senses and of sensation. At most, and then only at the onset, have pricking and formication been complained of. In one case recorded by Fischl, however, some loss of sensibility was remarked.

Just as the onset of the paralysis is gradual, so also it tends to disappear piecemeal. As a rule, the mode of subsidence is inversely to that of the onset, in such wise that the upper limbs are the last to lose and the first to regain their motility. Electrical excitability is restored *pari passu* with the return of movement until it is at the normal level. According to Cousot, galvanic excitability is the first to return as the muscles regain their contractility. However this may be, the electrical reactions between the attacks appear to be quite normal, although in one instance Dr. Goldflam noted some loss of electrical excitability in the small muscles of the hand which he was inclined to regard as evidence of degeneration. It should, indeed, be borne in mind that between the attacks most patients suffering from periodic paralysis enjoy perfect health and present nothing abnormal.

As will be seen, the schedule of symptoms just described comprises sufficiently distinct and constant characteristics to enable us to differentiate this affection easily enough from malarial paralysis. Moreover, in order to avoid any possible error of interpretation, I have deliberately left on one side all cases that could by any possibility be ascribed to malarial influence. For this reason I have ignored Cavaré's cases as well as those of Hartwig and Gibney, either on account of the beneficial action of quinine or of malarial antecedents, and this independently of the fact that, with the exception of Hartwig's case, none of these cases exhibited the symptoms of periodic paralysis as described above. There were disturbances of sensation, febrile reactions with attacks of shivering and heat, &c. For the same reason I have thought it well to discard an otherwise interesting observation by Seiler as well as cases by Bataille and Rockwell, which were examples of intermittent hemiplegia, probably of malarial origin, judging by the excellent effects that followed the administration of quinine.

The periodic paralysis, of which numerous examples, have been mentioned, as I have pointed out, has nothing to do with intermittent fever, and it is equally independent of malarial cachexia, since the cases which I have instanced were observed in healthy subjects free from any malarial antecedents. It remains to be seen whether any other infective malady may or may not play an active part in its etiology. Looking closely at the facts before us, this appears improbable. The only infective malady which has been met with in the antecedents of several of the patients suffering from periodic paralysis is scarlet fever. But, with the exception of Fischl's case, the fever was long anterior to the onset of the paralysis, and the virus of scarlet fever is not operative at such long intervals; moreover, paralyzes consecutive to scarlet fever, rare in themselves, are almost always cerebral.

With regard to the predisposing causes of the disease, sex does not appear to exert any influence, but it is quite otherwise in regard to age, the affection supervening almost invariably during adolescence, *i. e.*, between 10 and 25 years of age. One of the most interesting features of the disease is its family or hereditary character. This was noted by Chakhnovitch,

but was particularly emphasised by Cousot, who, out of eight children belonging to the same family, found four suffering from periodic paralysis, as did also their mother. Goldflam, moreover, insists on the family character of the malady, his remarks being based on observation of eleven members of one family. Taylor's two patients were brother and sister, and in five generations on the maternal side there had been no less than eleven cases of periodic paralysis. It is curious to note that the disease was almost always transmitted directly, that is to say, the members of the family who were themselves free from paralysis begot children equally exempt therefrom.

These facts deserve our careful attention, if only for the reason that no history of disease of the nervous system was discovered in this family any more than in that of the family referred to by Goldflam, beyond the occurrence of epilepsy in one member thereof, this one, as it happens, being free from paralysis. This fact does not diminish the importance of the rest of the series since it is established that periodic paralysis had shown itself in three successive generations of a family apparently exempt from any other neurotic tendency. The same family characteristic was noted by Hirsch, Mitchell, Buzzard, Oddo, and Audibert, so that it may fairly be described as an hereditary affection.

Under these circumstances, it appears reasonable to place periodic paralysis in the group of family diseases along with primary progressive myopathy, congenital myotonia, &c., the more so seeing that, from a clinical point of view, the paralysis in question presents certain points of resemblance with Thomsen's disease. We must take note, on the other hand, of the anatomical observations made by the same author on small, freshly-excised fragments of muscle. By this means Goldflam was enabled to satisfy himself of the existence of certain changes (hypertrophy of the muscle fibres, wasting of the primitive fibrillæ and vacuolisation), which are also of a kind to bring periodic paralysis into line with congenital myotonia. These observations have, moreover, been confirmed by MM. Crafts, Singer, and Goodbody.

However this may be, it is hardly possible for us, at this stage, to accept the hypothesis formulated by Chakhnovitch, according to whom this paralysis is merely a simple neurosis, involving more particularly the antero-lateral columns of the cord. The explanation offered by Cousot, who endeavours to show that the transitory paralysis is due to a sort of inhibition of the medullary centres, hardly commends itself for adoption, although a very similar hypothesis has quite recently been put forward by Putnam. The view that we have here to deal with an affection, strictly speaking, of the muscles is supported not only by the analogies of periodic paralysis with Thomsen's disease, and the presence of the above-mentioned muscular lesions, but also by the case recorded by Bernhardt, in which the attacks were associated with progressive muscular atrophy of the hereditary type. Moreover, even if we admit this explanation, it still remains for us to discover the cause of the morbid process thus attacking the muscular element.

According to Goldflam, it is due to a variety of auto-intoxication by substances that accumulate in the organism in the state of repose, an hypothesis which he has tried to substantiate by experiment, *viz.* by injecting animals with urine secreted during the paralytic attack. He discovered that the co-efficient of urinary toxicity was much higher during, than between, the attacks. He found, on the other hand, that the disappearance of the patellar reflex, which only takes place just before death in animals injected with urine passed *between* the attacks, is, on the contrary, an early symptom when urine passed *during* an attack is employed; the same remark, indeed, applies to the paralysis of the extremities. These experiments, however, gave no result in respect of the electrical excitability of the muscles.

Although the outcome of these experiments is far from conclusive, since Goldflam failed to reproduce experimentally the characteristic syndroma of periodic

paralysis with loss of electrical reaction, we are fain to admit that the hypothesis of an auto-intoxication is the most plausible and the best calculated to explain the paralytic phenomena and the injurious influence of repose (delayed elimination of toxins).

The etiology and pathogenesis of this affection being still obscure, we must not be surprised to find that the influence of the various therapeutical agents employed to combat it (bromides, iodides, strychnine, eserine, galvanism, &c.) should be in great measure negative. In view of the injurious influence of repose in the production of the attacks we might try massage and suitable gymnastic exercises as soon as the prodromal manifestations indicate the proximity of an attack. Nevertheless, it is difficult to avert the attack, and as a general rule the most we shall achieve will be to delay its supervention. Lastly, if one bears in mind that, according to Oddo and Darcourt, muscles faradised during the attack resume their motricity more promptly than untreated muscles, it might be worth while employing the current for a sufficiently prolonged period to the paralysed muscles during the attack.

## RECORD OF A CASE OF TUBERCULOUS SYNOVITIS OF THE RIGHT KNEE-JOINT

IN A BOY, ÆT. 8; ACCOMPANIED BY A NEW  
SUGGESTION AS TO THE PART PLAYED  
BY FOOD IN THE HUMAN ECONOMY (a)

By A. RABAGLIATI, M.D., F.R.C.S. Edin.

H. L., æt. 9 last March, was first brought to me on January 6th, 1904. He was pale and thin, and also limping. On examination I found a swelling of right knee-joint, the whole synovial membrane being thickened, so as to fill all the hollows of the joint with a gelatinous, more or less elastic feel all over it, while at the upper and outer part of the sac there was a special thickened and resistant part raised in the form, and about the size of a cricket ball. Whether this portion of the thickened sac was loculated off from the rest of the synovial apparatus was not certain. No fluid wave could be propagated from one part of the sac to another. This question was settled at the operation. There was no demarcation, although preparations were being made by Nature with that end in view (or at least adapted to that end). Had suppuration been allowed to occur, no doubt the suppurating part would have been more or less demarcated from the rest. However, when I saw the boy first, I did not think that operation would be necessary, and as I was very anxious to avoid interference, which would almost certainly have opened the joint, I recommended that the boy should go for treatment into the Children's Hospital. The limb was laid on a back splint, the knee being surrounded with strips of Scott's dressing pulled moderately tight, so as to give support. For diet I ordered a pint of milk daily, divided into four portions, to each of which an equal quantity of boiling water was added. I believe that tuberculosis is a disease caused by over-feeding beyond the requirements of the body; hence my recommendation that the boy should have only as much food as would be represented by 280 calories a day, in place of the 1,200 or 1,400 which the physiological authorities say is necessary for him. And the definition I venture to offer

of the disease tuberculosis is *not* that it is a condition caused by the growth of the *Bacillus tuberculosis* in the tissues and blood of the patient, *but* that tuberculosis is that state of the economy which favours the growth of *Bacillus tuberculosis*. The boy had been very delicate all his life. His parents thought they would not be able to rear him. He was continually taking cold, terrifying his mother by waking up in the night with attacks of spurious croup (*laryngo-tracheo-bronchial catarrh*). The least exposure or exertion seemed to give him cold. I think, in this connection, that in treating delicate children we forget that the definition of delicacy is that it is a state of low resistance to all sorts of labour, and, among the rest, to digestive labour. In our desire to feed such children sufficiently we over-do and over-feed, I think, and the children suffer from the excess of our zeal. Delicate children ought not to have their digestive resistance over-taxed any more than that of any of their other powers.

The child did not settle well away from his mother and family, and it was agreed that he should be taken from the hospital on January 24th, 1904, and treated at home. The diet recommended was, for a time, the same as in the hospital, and by-and-bye the same with half a pint of soup, brown or white, at dinner-time, with some cooked green vegetables and half a slice of bread. Total caloric value say 350 to 400. He did very well on this diet. All the pain disappeared with rest, and as there were no constitutional symptoms, I hoped for an improvement in the knee also. This hope, however, was disappointed, for after some weeks the knee was not better and, indeed, it seemed as though an abscess would be likely to form at a considerably later date. As at last I did not see any sign of subsidence of the tumour, and as I had seen an almost exactly similar case in which suppuration had occurred, which had penetrated through the synovial and muscular tissues even to the femur, I recommended that an operation should be performed for the removal of the portion of the sac chiefly affected. I was glad I did, for when, with the kind assistance of Mr. Miall, I cut down on it on February 20th, I found that the general synovial sac was thickened, that the special part of it which may be called the tumour was specially so, and that it seemed to be intimately adherent to the vastus muscle and other parts of the quadriceps extensor, and also that the contents of the synovial sac, and especially at this place, were of a dark grey or almost black colour. I felt convinced that it was not likely to resolve, and that, in fact, the condition was in process of eventuating in the formation of suppuration, which from former experience I felt sure would not have stopped till it reached the femur. I emptied the contents and removed the bulging part of the sac, which was about the size of an orange, bringing the edges together as well as I could with catgut sutures, the whole operation being done under aseptic conditions as far as possible, although, as you may perceive, I attach far more importance to *internal asepsis*—i.e., to proper nutrition—than to those multitudinous external ablutions which pass under the name of asepsis. I examined the inside of the joint with the finger, but found no ulceration of cartilage. Then I brought the whole wound together with silkworm-gut sutures, passed deeply, after having made the parts as dry as possible by pressure between

(a) Read before the Bradford Medico-Chirurgical Society, November 15th, 1904.

mops wrung out of Hg.I<sub>2</sub> solution 1 in 5,000. The recovery was satisfactory. Even during the first day and night the pain was not intolerable, and I used no morphia. On March 11th, there were no signs of constitutional disturbance, although there was a considerable amount of suppuration about the wound and the exudation of some tuberculous pus. On March 28th, I asked Mr. Miall to give me his opinion again on the whole case. The wound was then nearly well, there being only one small granulation excrescence remaining at the upper part. The patella was free and movable, as it has remained ever since. The hollows of the joint showed very much as on the other side. Boy looking well; no fever; sleeping well; eating well; bowels acting. Diet, a pint of milk daily, with half a pint of soup and a slice of brown bread. I had removed the back splint on March 24th, and asked the mother to bandage the limb afresh morning and evening. Total calories from food as far as I could gauge them, not more than 500, against the 1,200 or 1,400 recommended to an ordinary child of that age, or the 2,000 or more recommended under prevailing ideas as suitable for a child suffering from a wasting disease like tuberculosis.

Now, in case any gentleman may say or think that this was not a case of tuberculous, but only of simple inflammatory synovitis, I have to mention that I sent the boy again to Mr. Miall on account of a strumous irido-keratitis which was very severe, and accompanied by so much photophobia as to induce temporary functional blindness. Mr. Miall thought that it would be well to take the opinion of a specialist, whereupon the boy was sent to Dr. Little in May. Dr. Little may remember the case. At any rate, he confirmed the diagnosis of strumous keratitis and iritis, and gave a hopeful prognosis, which has been verified, the boy being now almost well, and having been able to attend school since the beginning of the autumn term. The knee has been quite cured long since, the boy being able to walk and even run a short distance without limping. I do not know how it might be if he ran for a long distance, but at any rate he does everything which his companions do at school. (a) He is in no sense an invalid, and his parents say he is stronger and has fewer colds than ever before in his life, and has, in fact, been converted from a delicate boy, constantly ailing with colds, bronchitis, &c., into a boy who, if not exactly robust, never ails anything. The cough which used to wake him up in the night never troubles him at all now. His diet on one day last week, taken at random, was: in the morning, on going out to school, a cup of cocoa. His mother mentioned as a point of interest that he never seems cold on this. At dinner he had an egg (sometimes he takes a couple of ounces of mutton) and a slice of bread, say two ounces, and about 1½ inch square, or say 2½ square inches of a fruit pasty. In the evening he had another slice of bread and butter, a glass of milk, and about ½ oz. to 1 oz. of cheese. The caloric value of this, so far as I am able to gauge it, is about: Bread, 138; bread and butter, 208; egg, 70; pasty, say 70; cheese, 112; milk, 280 calories—total, 878 calories, if, indeed, he had as much as this, for I do not think he took a pint of milk, and I doubt if he had as much as an ounce

(a) His mother has since informed me that the boy does not limp at all, even if he runs a long distance.

of cheese. For many months he took only the morning cup of cocoa, a slice of bread with soup at dinner-time, and half a pint of milk in the evening, a diet amounting to the value of about 350 calories, and which I call practical monositeism. He is now dissiteous, and I have advised his mother to keep him to this. He has gained about a stone in weight since I saw him in January.

Now, gentlemen, I come to the second and main part of my communication. I will put what I have to say in the form of a suggestion. It has been suggested to me, (a) and I in turn suggest to you, that we ask ourselves the question, Is food to any extent, and if so, to what extent, the source of the external energy exerted by the body?

Do not please put this question aside as unworthy of consideration. It will be put to you, I venture to say, on other occasions than to-night. I want to ask whether the analogue of the human body considered as a machine is not rather the electric motor of the electric engineer than the steam engine of Watts; suggested as an analogy by Liebig and Playfair, Moleschott, Ranke, and the rest of the modern authorities. The difference is enormous. If the analogy is the steam engine, then the body gets the energy which it exerts externally (and which, for the sake of brevity, I shall call its external energy), from the potential energy of its fuel; and food is the fuel. But if the analogy is, properly speaking, not the steam engine but the motor, then the body gets its external energy not from its food or fuel, but through the analogue of its wires, or even wirelessly—*viz.*, from the illimitable stores of energy with which in Nature it is surrounded. Let us think of this. It seemed incredible at first, but the more I think of it the more does the idea fascinate and hold me. What seems to me to be the truth is this: *Qua* internal energy—*i.e.*, so far as nutrition and the maintenance of the animal heat are concerned—the body does seem to be analogous to a steam engine, and gets its energy for these two purposes from the food. The maintenance of the animal heat is a serious task. The body of a man weighing, say, 120 lbs., has to be maintained at 40° or 50° or 60° F., above that of the surrounding atmosphere. Even if the specific heat of animal tissue is the same as that of water, this implies an important amount of work. Some years ago, I made out from somewhat rough experiments that the specific heat of animal tissue was about 780 foot pounds. If this is nearly correct, the internal energy of the body will amount (besides the energy of simple nutrition) to  $\frac{120 \times 60 \times 780}{2,240}$  or about 2,500 foot tons of energy, a very considerable amount; and it is for this purpose that I believe food to be necessary for the body. But the *external energy* of the body, I suggest to you, does not come from the food, nor even from the body. It comes from those stores of energy with which the body is surrounded, and in which it lives and moves. This idea does not contravene the law of the conservation of energy. The body no more creates its external energy than the motor does. Like it, however, it transmits and transforms the energy which it receives. I have said what is the function of food; and the function of the engineer or owner of

(a) By Mr. Hereward Carrington, of New York.

the body—*i.e.*, of each person, is to see that all the points of contact, so to say, of the machine, all its electrodes and avenues and channels, are bright and clear, so that there shall be as little hindrance as possible to either the inflow of energy in the form of power, or to its outflow in the form of work done. If the internal work of the economy is either underdone or overdone, its work as a motor must be interfered with. If the nutrition is too little, the receptive power of the motor will be checked and unduly diminished. If the nutrition is overdone, then the receptive power will also be diminished, because the points of contact or the electrodes will be dull and clogged. And when the nutrition is properly managed, the motor will work up to the measure of its capacity, receiving as much energy as will fill it, and transmitting and transforming it into external work. It seems a very simple theory, but a revolutionary one, and yet very probable. Can we adduce any arguments in its favour? I think we can.

1. Urea, uric acid and urates are far more the exponent of the state of the nutrition than of work done. A man may part with these, and often does so, when he is doing no external work at all, when, for instance, he is lying in bed. 2. In sickness he gets rid of large quantities of these effete materials when he is doing no external work, and, indeed, cannot do it, mainly because before he was sick he overloaded his economy with nutritive material. Such experiments as Weston's walk showed that these excreta were not proportioned to the amount of work done. When the pedestrian fevered, these products vastly increased, but, of course, then he could hardly walk at all. 3. Although lifting weights bears some relation to the size of the body, intellectual, moral, spiritual, artistic, organising and governing work bears no predicable relation at all, either to the amount of food consumed or to the size of the body of the actor. 4. How does fasting so often elevate the bodily temperature and increase the strength, if we receive our external energy from the food? 5. Why do we go to bed when fatigued and not to the dining-room? How is it that we need sleep at all? Other reasons and arguments might be adduced, but I will spare your time and end with this one. Professor Bose has recently shown that the energy of dead things (so-called) and of living things, or vital energy, is the same. And he has shown some other very remarkable facts, as, for instance, that a metal wire may be poisoned more or less, so far as the power to let an electric current pass is concerned, by treating it with various agents which also act as poisons to living things. The energy is prevented from flowing into inorganic things by changes effected by such substances, and so the dead things cannot transmit, much less transform, such energy. So let us see to it that our constitutions are kept so clean, healthy and bright that the vital energy surrounding us shall have free access into the motors of our bodies, there to be transmitted and transformed into the best work of each according to our several capacities. I make no apology for bringing under your notice this further attempt on my part to harmonise the practical cure of this boy with high theory as to the meaning of tuberculosis, and the analogues of the animal machine to steam engines and motors, or its relations to the all-embracing law of the conservation of energy.

## Transactions of Societies.

### WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

MEETING HELD DECEMBER 2ND, 1904.

C. M. TUKE, Esq., President, in the Chair.

DR. A. E. RUSSELL read a paper on

#### DIAGNOSIS OF ACUTE ABDOMINAL DISEASES.

The first part of the paper dealt with methods of examination and their order of procedure, and great stress was laid upon the necessity of thorough examination of the thoracic viscera, the rectum and vagina. The general condition of the patient, with especial reference to the pulse, facial aspect and vomiting, was pointed out, as almost of equal importance as local abdominal signs. The author strongly deprecated giving opium in cases of doubtful diagnosis. The advisability of early operation in grave cases was insisted upon. Consideration of the relative frequency of the different varieties of acute abdominal disease, and of the age and sex of the patient, as illustrated by a large series of cases, was very helpful in forming an opinion based upon probabilities.

Mr. L. A. BIDWELL considered that there were two distinct questions raised in Dr. Russell's paper, *vis.*: (1) that of diagnosis of the lesion present, and (2) that of the necessity of immediate operation. He affirmed the existence of a rapid pulse and low temperature to be the gravest symptom in acute cases, and nearly always demanding immediate operation. He drew attention to the differential diagnosis between appendicitis and suppurative gall-bladder. In the former the rounded edge of the tumour is *above*, and there is an area of resonance between it and the liver, whereas in the latter, the rounded edge is *below*, and the dullness is continuous with that of the liver.

Mr. J. D. ARMOUR did not agree with Dr. Russell with regard to the question of the facies, and related three acute cases, none of which showed by their appearance the slightest sign of their condition.

Mr. E. P. PATON pointed out one feature not mentioned by Dr. Russell, which not infrequently occurs in acute cases. He referred to the *quiet period* following immediately after the acute onset, and warned practitioners not to be misled by this, as often the acute symptoms return in an aggravated form.

Dr. MANSELL MOULLIN expressed his surprise that so small a proportion of gynaecological cases occurred in abdominal surgery, and alluded to the frequency of acute abdominal trouble occurring in women of the child-bearing age, the most serious cases being those of hæmorrhage due to tubal rupture.

Mr. McADAM ECCLES was struck with the high percentage of cases of intussusception, *vis.*: 16 per cent., and thought it to be accidental for the years mentioned. He also alluded to a point not mentioned by Dr. Russell, *vis.*, hyperæsthesia. With reference to the question of the administration of morphia, Mr. Eccles advised *one* dose subcutaneously when the patient had to be removed, but if an operation is to be undertaken at the patient's own house without any removal, he strongly advocated that no morphia or opium be given. Mr. Eccles also mentioned that occasionally there were two or more causes of acute abdominal symptoms in the same patient.

Dr. SEYMOUR TAYLOR pointed out that indican is almost invariably present in the urine in acute abdominal cases, and considered it of use in deciding the diagnosis between injury to intestines and peritoneum or muscles. As to latent symptoms in cases of peritonitis, he submitted that the quiet pulse is the indication of the condition of shock, which is the first and most prominent condition of abdominal injuries, soon succeeded by rapid pulse and temperature. He considered pain to be by no means a necessary guide to threat of lesion.

Mr. ASLETT BALDWIN said that the cutaneous

hyperæsthesia mentioned by Mr. Eccles is of great interest, at the same time the symptom is very misleading. If present in a case of appendicitis, as an instance, and it passes off without amelioration of other symptoms, it is a sign of grave importance, and indicates immediate operation. With reference to the prominent symptom of shock mentioned by Dr. Seymour Taylor as being invariably present, Mr. Baldwin quoted cases of severe abdominal injuries where there was not the slightest sign of shock.

Dr. A. E. RUSSELL, in reply to Mr. Bidwell, commented upon the difficulty in the diagnosis of appendicitis and suppurative gall-bladder. In answer to Dr. Seymour Taylor, he said that pain commencing definitely in a region such as the iliac fossa or gall-bladder was probably indicative of the organ at fault, but fully agreed with Mr. Taylor that when the pain was referred vaguely to the umbilicus or general abdominal wall, it was valueless.

#### LIVERPOOL MEDICAL INSTITUTION.

MEETING HELD DECEMBER 15TH, 1904.

DR. J. R. LOGAN, Vice-President, in the Chair.

DR. MIDDLEMASS HUNT showed a case of Primary Syphilitic Infection of the Nostril. The chancre was situated on the left side of the septal cartilage. The patient, a youth, æt. 17, had suffered from one-sided nasal obstruction and discharge for two months. There was considerable glandular enlargement on the affected side, and within the last fortnight a characteristic rash had appeared on the face and body. No history could be obtained as to the source or mode of infection.

Mr. DOUGLAS-CRAWFORD read a note on two cases of Actinomycosis. The first case was that of a ship's surgeon, the skin of the flank being the affected area. In the second case the patient was a butcher, and the sub-maxillary region the part affected. Excision was performed in both cases with satisfactory results.

Mr. K. W. MONSARRAT read a note on Constriction of the Ureter. After enumerating the different types of constriction, he related three cases illustrative of the condition. The first was a case of true stricture of the pelvic ureter which gave rise to symptoms mistaken for those of appendicitis; a cure was effected by dilatation of the ureter from the bladder. The second case was one of Hydronephrosis, in which the ureter was flattened against and bound by adhesions to the hydronephrotic sac; a plastic operation upon the ureter was successfully performed. In the third case there was Pyonephrosis with stricture of the ureter at its junction with the renal pelvis. Mr. Monsarrat suggested that in the etiology of similar cases of primary pyelitis of obscure origin, renal stasis caused by ureteral obstruction probably played an important part.

Mr. George Hamilton, Mr. Rushton Parker, Mr. R. A. Bickersteth, Dr. R. J. H. Buchanan, Mr. F. T. Paul, Dr. N. E. Roberts, Dr. W. Alexander, Dr. T. B. Grimsdale, Mr. G. P. Newbolt, Mr. Litler Jones, and Mr. Damer Harrison took part in the discussion.

Mr. RUSHTON PARKER read a note on  
PERINEAL PROSTATECTOMY.

He practised the operation as described by Dr. Parker Syms at the Manchester meeting of the British Medical Association in 1902. He had thus operated upon eight cases between December, 1902, and November, 1904. The ages of the patients varied from 59 to 76 years, five of them being over 70 years of age. The prostates removed varied in weight from  $\frac{3}{4}$  oz. to  $\frac{1}{2}$  oz. All the patients had been unable to pass urine without the use of a catheter before operation, and all had subsequently become enabled to hold and to pass water comfortably, except one case which terminated fatally. The after-treatment consisted in bladder drainage by means of a long tube for two to five days, and plugging of the prostatic gap for twenty-four hours with strips of gutta-percha tissue in preference to gauze. The gutta-percha strips can be removed

without disturbing the patient or causing hæmorrhage. A catheter is passed daily and the bladder washed out.

Dr. W. Alexander, Mr. Douglas-Crawford, and Mr. G. P. Newbolt took part in the discussion.

Mr. C. THURSTAN HOLLAND read a note based on a case of Central Round-celled Sarcoma of the Upper End of the Femur. The patient was under the care of Mr. G. P. Newbolt, at the Royal Southern Hospital. A series of radiographs was shown, illustrating various diseases of the bone bearing on the subject. The X-ray appearances of central round-celled sarcoma, myeloid sarcoma, periosteal sarcoma, abscess of bone, &c., were discussed. The fact that operations for malignant bone disease were so frequently followed by return of the growth was considered to be probably due to the condition being diagnosed too late. By the help of a good radiographic examination, suspicion might be cleared up very much earlier in the history of these cases, and thus enable better results to be obtained by means of operative treatment.

Mr. G. P. NEWBOLT described the clinical history of the case. He had performed amputation of the hip-joint, but the patient died the day following the operation.

Mr. R. A. Bickersteth, Mr. Rushton Parker, Dr. W. Alexander, and Mr. Damer Harrison took part in the discussion.

#### SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

MEETING HELD DECEMBER 16TH, 1904.

DR. FREDERICK TAYLOR in the Chair.

DR. C. J. MACALISTER (Liverpool) opened a discussion on

SUDDEN AND UNEXPECTED DEATH IN CHILDREN, dealing mainly with a class of cases which appear to be due to toxic influences. He referred especially to the sudden deaths which take place in institutions devoted to the care and keeping of children. He quoted several cases in his own experience where children, sometimes with hardly any prodromal symptoms, in other cases with a few hours' suffering from headaches and diarrhoea or vomiting, had died in a cyanosed condition from asphyxia. At the *post-mortem* examinations sometimes a very localised patch of pulmonary consolidation had been found, at others a general congestion of the lungs, such as might be found in any case of suffocation, but no lesion of the nervous system had ever been discovered to account for these deaths, and he considered that they were probably due to a poison which exerted its influence upon the respiratory centre. In the institutions in which these deaths had occurred, it was found that collective bathing was frequently in vogue, and Dr. Macalister pointed out how saturated the water became with organic matter and micro-organisms after a number of children had been washed in it, and that in one school where this method of bathing was altered, about five years ago, these deaths had practically been stamped out, and the general health of the children had been vastly improved. Dr. Macalister quoted a case from the practice of Dr. Harris, of Birkenhead, of an appallingly sudden death in an infant, which had previously been healthy, and he felt disposed to ascribe this type of case (as suggested by Buzzard long ago) to infantile paralysis attacking the centre of the vagus, and suggested that in all probability the curious and selective poison which caused this disease might be discovered in some flaw in nursery hygiene. Other examples of toxæmia referred to were those in which hæmorrhage occurred from the stomach and cases of hæmorrhage into the suprarenal bodies, and a death from hæmorrhage from the carotid artery was also recited as having complicated scarlatina. In conclusion, it was pointed out that in some cases, which had been thought to be simple diarrhoea or some unimportant febrile

disturbance, had died suddenly and had proved to be examples of enteric fever; and he mentioned also examples of sudden death following diphtheria, in fulminating small-pox, and in gangrenous varicella.

Dr. J. PORTER PARKINSON, in considering the functional causes, referred to heart failure and sudden death in marasmus, to convulsions, usually causing death by asphyxia, to laryngismus stridulus as a rare cause, and to spasm of the glottis resulting fatally from pressure of an enlarged gland on the recurrent laryngeal nerve. The pathological changes in these conditions and in "over-laid" babies were described. Excessive emotion was a rare cause of sudden death in children.

Mr. J. THOMSON WALKER discussed the subject in relation to the thymus gland and the status lymphaticus. He summed up the clinical pictures of the latter constitutional state as (1) no previous evidence of illness; (2) previous restlessness, &c.; (3) thymic asthma. In many cases there is associated rickets. In others there is disease which might be sufficiently serious to end fatally without the addition of this peculiar lymphatic state. Possibly the condition might account for still-birth occasionally, and for deaths following violent emotion, sudden shock, and anæsthesia. Hypoplasia of the heart and coarctation of the aorta have been found in some of these cases, and sometimes an enlarged thyroid. Mr. Thomson Walker laid stress on the association of rickets, adenoid tissue in the naso-pharynx and laryngismus; also on the state of lymphatism as an important factor in producing a fatal issue in an otherwise simple illness. He discussed the pathology in reference to the pressure and toxic theories, an excess of thymic secretion or some other poison. Cases might be diagnosed from evidence of an enlarged thymus, if there were anything to suggest lymphatic hyperplasia.

Mr. A. H. TUBBY considered the surgical cause in reference to circulatory conditions such as hæmorrhage in the new-born, scurvy, ulcer of the stomach or duodenum, hæmorrhage during operation, and thrombosis; and to shock and the means of diminishing it. The shock following irrigation of the pleural cavity he ascribed to the nature of the fluid rather than to the actual irrigation, provided there were a free exit for the fluid. Among toxic conditions, he mentioned the absorption of iodoform and carbolic acid, toxins, and uræmia. Many other surgical causes connected with the throat and larynx, with mechanical effects from tying the hands of a restless child, with foreign bodies and pressure on the trachea, were also considered.

Dr. J. BLUMFELD referred to subjects in connection with anæsthetics, confining his remarks to those cases of sudden death in children during or after anæsthesia, in which the ailment had caused no loss of general health. The importance of a skilled anæsthetist for infants could not be over-estimated. Death in the pre-anæsthetic stage almost always occurred with absolute suddenness, and was due to too strong a vapour of chloroform.

Dr. PAGE drew attention to the occurrence of sudden death in the course of disease not necessarily fatal, such as phthisis. These cases were, he thought, due to an over-dose of toxin, an auto-intoxication, the patient having been living, as it were, on the edge of a precipice. He thought that one important result of the discussion would be to draw attention to the means necessary to prevent a sudden fatal issue in cases requiring surgical treatment, and from anæsthesia. In the toxic cases it was difficult to foresee a remedy.

Dr. YOUNG thought lymphatism more common than supposed in both children and adults, basing his conclusions on *post-mortem* examinations. Sudden death was frequent in exophthalmic goitre, especially after operations, and in myasthenia gravis, in which the thymus was persistent. Recently he had found the thymus persistent in several cases of sudden death.

Dr. EDMUND CAUTLEY insisted on the importance of the subject to the general practitioner, for most of these cases came under their notice, and they had

to make the autopsies and give evidence before the coroner. He detailed two such cases in which death had been ascribed to "mesenteric disease" and to typhoid fever. In neither were the history of the case, the appearance of the child shortly before death, or the *post-mortem* results sufficient to warrant these diagnoses, and he was inclined to ascribe the deaths to the status lymphaticus. In many deaths in the course of marasmus in infants, though the child was progressing favourably, it was impossible to assign an exact cause. Some died from syncope, others during a slight convulsion, and in many no cause could be found.

Dr. L. GUTHRIE remarked on congenital syphilis as a cause, and on the effects of too rapidly curing an extensive cutaneous eruption.

Mr. G. PERNET spoke in support of his views.

Mr. ARTHUR EDMUNDS thought that evil effects from sudden cure of eruptions were due to toxic absorption. He had seen similar results due to extensive skin grafting.

#### THE MEDICO-LEGAL SOCIETY. MEETING HELD DECEMBER 13TH, 1904.

SIR WILLIAM COLLINS, M.D., President, in the Chair.

Dr. HARVEY LITTLEJOHN exhibited four specimens of medico-legal interest.

Dr. R. R. RENTOUL read a paper on DEGENERATION: ITS CAUSES AND PREVENTION, with Reference to the Proposed Sterilisation of Certain Degenerates. The Census of 1901 revealed nearly half a million degenerates. The publicity of the certification of "the cause of death" prevented many inebriates being recorded in our national statistics; he would have the fact of death certified to the personal representatives of the deceased, the cause to the Registrar-General. From an exhaustive series of tables he exhibited, he concluded that the ratio of the mentally or physically unfit was 1 in 5 of the population, and the financial cost of their upkeep was not far from fifty million pounds annually. Immigration of undesirable aliens added to our unfits, emigration of our own healthy stock drained us of many of our fit. He would exact compulsory sterilisation (by vasectomy, salpingotomy, &c.) in the cases of idiots, the congenital deaf, confirmed epileptics, certain backward children, &c., and would allow voluntary sterilisation where there was obstetrical danger in a woman being pregnant and being delivered. In the compulsory class there should always be needed the sanction of the Commissioners in Lunacy.

After letters had been read from the Earl of Meath, M. Max Nordau, Mr. H. G. Wells, and Mr. T. J. Barnardo, F.R.C.S.E., an animated discussion was opened by the President.

Dr. JAMES SCOTT (Brixton Gaol) favoured segregation of the unfit, by an extension of the Idiots and Imbeciles Act (1886); Dr. Rentoul's proposal, if carried out, would add another burden to the life of the medical man.

Dr. H. B. DONKIN (Prison Commissioner) demanded a definition of "degenerate"; many prisoners were without this class.

Dr. T. B. HYSLOP (Bethlem Asylum) said degenerates increased with the progress of civilisation; among the unemployable unemployed the inhabitants of public institutions must be numbered. London was "a carbuncle on the neck of England," its areas of over-crowding were "acne spots" upon the body politic; treatment must be dietetic; the "food" imported should be supervised and unhealthy material should be expurgated. Dr. Rentoul, as others before him, had caught a "sperm-whale." England and Englishmen elected to "stand upon their heads," and necessarily experienced intellectual obfuscation—we must get right side up.

Sir JOHN McDUGALL, L.C.C., held it was the irregular and not the strenuous life—the Strand, not the East End—which filled the asylum; as a visitor

he often felt he was doing a social wrong in discharging the mentally insane when they were "recovered."

Dr. F. J. SMITH thought that at least it would be administratively practical to deal with those charged with homicidal or other personal violence; the public should not be told too much of the methods employed.

Mr. ARNOLD WHITE had advocated similar measures nearly two decades ago; lately, an hysteria had afflicted public opinion, its abnormal vibrations differed greatly from our pristine steady national character.

Mr. BERNARD SHAW regretted Dr. Rentoul had only had a medical, not a scientific, education! Medical men should instruct the public with authority, but their teaching was compromised by ignorance. We did not know what degeneracy nor heredity meant. If we got rid of the diseased we should lose many interesting people; epilepsy may be but a perverted form of energy. The terms used were relative to our social ideas; he could imagine an insane majority segregating a sane minority. Surgical and "chalk and opium" methods were applied too frequently by medical men to social problems. The population was the essential factor, and its quality was more vital than its quantity; we must breed from a good human stock even if the "sacredness" of marriage suffers.

Dr. C. R. DRYSDALE believed medical measures were not exhausted; the families of medical men were smaller than formerly.

Earl RUSSELL feared a good case had been overstated. Society interferes with Nature's weeding processes.

His Honour Judge RENTOUL faced this question practically day by day in his court; definition and differentiation were necessary.

Mr. GEORGE PERNET affirmed our ignorance of the nature of heredity.

Dr. HOWELL EVANS, with a large experience of London's invalid children, held that these weaklings were so either from accident or from heredity; treatment differed in each case; for the former ante-natal measures might do much.

Sir WILLIAM COLLINS, in summing up, deprecated loose talk where precise legislation was desirable. Weissman did not say the last word on heredity, as Watson's recent experiments on the transmission of acquired maternal immunity showed. The recent Commission on Physical Deterioration was more optimistic than the present discussion would indicate—"the inherited mean" must have been forgotten. Environment was regaining some of its temporarily discredited influence. The ethical aspect of the question had been ignored; what would be the state of society with numbers of sterilised criminal eunuchs roaming at large? He had little confidence in the short cuts of benevolent despots, and should hold up his hand against compulsory mutilation.

Dr. RENTOUL having replied briefly, the meeting terminated. Seven new members were enrolled.

PARIS, December 24th, 1904.

### TREATMENT OF FOREIGN BODIES IN THE EAR.

THESE are habitually divided into two classes—live bodies and inanimate bodies. The former consist generally of fleas, grasshoppers, or earwigs, which penetrate into the ear during sleep, while others are bred in the ear, from eggs deposited by flies, and these eggs produce worms or larvæ. Inanimate bodies are as variable as those found in the nose—pearls, boot buttons, pebbles, beans, grains of every kind, plugs of cotton wool, paper, &c. These may remain some time without causing any trouble, but generally they provoke buzzing, vertigo, nausea, vomiting, headache, and sometimes epileptiform convulsions. Symptoms that resemble cerebral disease (meningitis), and children have been treated for this affection.

If the foreign bodies are angular, pointed, infected, if they are capable of becoming swelled by humidity, if they are insects or their larvæ, they provoke violent inflammation with suppuration of the external meatus. The tympanum itself soon gets inflamed and otitis of the middle ear with all its complications sets in.

The treatment of these foreign bodies should always begin with repeated injections which, if persevered in, frequently succeed. If the body can be reached easily, a forceps or a crooked hairpin may be able to extract it. If, on the other hand, the symptoms are grave and threatening from penetration of the tympanum, the situation renders more radical means imperative. Either extraction should be made under chloroform or an attempt will be made to enter the middle ear and remove the obstruction.

### TREATMENT OF SCIATICA.

A simple yet effective method of relieving this painful affection will be found in the following:—

Nitrate of strychnine, 2 grs.;  
Water, 3½ oz.

A full Pravaz syringe injected daily in the region. Excellent results.

## Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, December 24th, 1904.

At the Medical Society, Hr. Riese, related some observations on the

### SURGERY OF THE GALL-BLADDER.

He first spoke on the origin of calculi. Naunyn and his school had shown that stagnation of bile and infection of the biliary passages gave rise to gall-stones; Courvoisier had recognised this, as he looked upon gall-stones as a purely local disease. The view of Ewald that there must be a disposition to the disease was not of much importance. The infection generally proceeded from the intestines, but it might come to pass through a hæmatogenous channel. The speaker himself had seen cholelithiasis develop in connection with pneumonia. He related two cases of severe cholecystitis with strepto- and staphylococcus infection in which he was able to cultivate the cocci out of the bile obtained at the operations. In one case where the patients suffered from severe gonorrhœa, he assumed a gonococcus infection.

The colic did not come from active contraction of the bile-passages, as it came on even when the calculus was imbedded in a sac, but it arose from infection of the bile-passage, possibly, as Wilms assumed, from dragging on the peritoneal covering.

Jaundice also was generally the expression of an infection, as it often came on even when there was no hindrance to the flow of bile. That it came on when concretions blocked up the whole choledochus was, of course, understood.

As regarded indications for operation, in cases where there was no infection of the bile-passages one might wait in calmness if the gall-bladder was not swollen, or if the patient did not press for an operation. If there were changes in the gall-bladder it might be removed or one might content oneself with drainage. Hydrops of the gall-bladder called for operation only when it caused serious trouble. In chronic closure of the choledochus one must, of course, operate. Even in acute closure one might operate with confidence, no bleeding need be feared.

In very acute cholecystitis, in Körte's opinion operation should be performed at once, and here extirpation of the gall-bladder, even in the face of great difficulties, was to be preferred. In twenty-five such operations in which the speaker had repeatedly found abscesses in the walls of the gall-bladder, he had only lost three. He had also performed a successful operation in a case of acute diffuse cholangitis in which he had opened quite a series of abscesses in the wall of the gall-bladder, and had drained the bladder for a lengthened period.

When carcinoma of the gall-bladder was suspected

at least a preliminary laparotomy should be performed, when some operation perhaps only palliative, might be rendered possible.

He had performed 55 cystectomies and 30 cystotomies; he had performed a total of 104 operations on the bile-passages, with 16 deaths.

As to the question of recurrences, it must be borne in mind that when the case was one of turning aside an imminent danger, the choledochus could always be looked for. That calculi originated primarily in the liver was improbable; intra-hepatic stones only occurred when extra-hepatic processes had been at work.

Hr. Körte agreed with the speaker in all essential points. He almost always performed cystectomy, as recurrences unquestionably took place after simple cystotomy. Disposition undoubtedly played a part, for bile stasis and infection by themselves did not cause stones. The gall-bladder might, however, be full of pus and the choledochus closed without any stone being present. Whether ectomy of the gall-bladder was a certain preventive of recurrence was at present questionable.

In the acutest form of cholecystitis and in closure of the choledochus the indication for operation was a vital one. There first of all life had to be saved, whether recurrence was likely or not. In the simple form of cholelithiasis, however, we must not be too free with our indications, and must operate only when patients wished us to do so.

Hr. Israel mentioned the not infrequent occurrence of gall-stone and renal colic in the same patient, and then spoke in favour of a stone-forming disposition. The influence that drainage had in acute diffuse cholangitis was not explained. It could not be the flow of bile that induced recovery as the quantity of it was much too small.

Hr. Roth related two cases in which a year after cholecystotomy, fresh colic came on with peritonitis. The autopsy showed hepatic calculi in both cases. A stone had burst the cicatrix of the choledochus and had caused the peritonitis.

Hr. Mellin spoke on the

#### INJECTION OF THIOSINNAMIN IN CICATRICAL CONTRACTION.

He mentioned numerous cases, but could furnish no satisfactory explanation of the peculiar action of thiosinnamin injection. He showed a woman who had had a series of injections made on account of cicatricial contraction from burns on the arms and face. The preparation employed was a 10 per cent. solution with addition of glycerine. Considerable improvement was shown in the contractions.

Hr. Riere confirmed the observation and said that an ectropion of the eyelids had simply disappeared after the injection.

Hr. Mankiewicz had observed improvement in strictures of the urethra, but after a time the old condition returned.

Hr. Riere injected around the cicatricial mass and not into it. He had seen no development of ulcers.

## Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, December 24th, 1904.

#### PREGNANCY AND UTERINE INVOLUTION.

The discussion of this interesting paper by Halban gave rise to an expression of diverse opinions on the function of pregnancy. Halban contended and gave evidence from examples that the monthly periods of the mother acted on the foetus *in utero* on and after the eighth lunar month of gestation. This, he concluded, was amply proved by the genitalia of the foetus being much larger at birth than what they are years after. All agreed that the breasts of the female and the prostate of the male were greater at this period.

Hofbauer was opposed to this theory of Halban, and said that he had had the opportunity of examining the mucous membrane of the uterus in twelve cases, and

only found one where changes had taken place, although ripe follicles in the ovaries were discharging ova. The size of the uterus was due, according to his opinion, to the addition of fibrous tissue and not muscular tissue, as was generally supposed. This may be the result of oedema or its proximity to the bladder. It is too early to conclude that the poison generated in the placenta is the morbid cause of eclampsia.

Fellner was of opinion that the ovaries were as active during pregnancy as before it, as we find follicles in every stage of their life history, even to bursting and leaving the ovaries, while the menstruation wave can be traced along the mucous membrane, leaving nothing but the menstrual discharge to complete the phenomenon. It is quite possible that the material from the ovaries passes on to the foetus and produces in it the phenomena described by Halban.

Tandler remarked that the watery production of the embryonal tissues was generally well known without attributing all this fluid accumulation to the placenta alone.

Mandl thought that this idea of enlarged uterus in the new born was not new, but had its origin in Baier, of Strasburg, who pointed out long ago that the uterus of the foetus *in utero* resembled one at puberty more than it did at any intervening period when involution really occurred. Under any circumstances investigations in this direction must be accepted with great reserve, as the cases must be few where actual demonstration can be accurately carried out. The menstrual changes in the mucous membrane was supported by an ovarian activity, but when we meet with parturition going its usual course after the ovaries have been removed, and the menstrual changes still present, we ought to pause and await more accurate knowledge. But these theorists are not satisfied with the ovarian secretions being the only cause; they tell us in the next breath that that phenomenon is caused by the secretion from the placenta. The hypotheses start out with the assumption that the ovarian secretion first stimulates the placenta to secrete.

Zappert thought that oedema during pregnancy was one of the peculiarities of gestation, and particularly in the surface of the foetus, which showed signs akin to this after-birth in parts of the skin, scrotum, symphyses, and inner surfaces of the thighs.

Halban, in replying, said the menstrual changes in the uterus could not be affected by ovulation, as careful section of the ovaries could not discover any follicles. It might also be noted here that in elderly children, though ripe follicles are present in the ovaries, no change can be observed in the uterus. These facts still add to our difficulty of demonstrating a close alliance between ovaries and uterus. If this be taken along with the fact that castration of a female during pregnancy in no way interferes with the course of gestation, it must be admitted that the ovaries have no influence over the foetus during pregnancy, and those genital changes so frequently observed in the foetus must be due to placental stimuli, as pointed out by many independent investigators.

#### URTICARIA XANTHELASMOIDEA.

Nobl showed a child, *æt.* 2½, covered with an exanthematous eruption varying in size from a millet seed to the size of a groat. The only parts escaping were the face, palms of the hands, the hairy scalp, and the soles of the feet. This rash had yellow tops, fading in the base to a coffee colour, each swelling having a peculiar soft, pliable feeling as if it were loose substance. The finger nails were irregularly formed and raised, having a brown pigmentary appearance outlined with a white ring merging into the surrounding normal tissue. This case deviated from former descriptions in so much that all former histories tell us that these tubercles are usually disseminated in groups over the body or in circinate plaques, while Nobl's case is universal. The disease seems to have commenced acutely about the fourth month of life. The first place of appearance was the trunk, whence it radiated over the limbs, &c. No burning or itching.

nor excoriation appear to have been present at any time in its history, therefore no general disturbance, rhachitis, or other changes were noted.

Tilbury first described this disease in 1875 as xanthelasma, from its clinical appearance, although he found it in many cases associated with urticaria, and presumed that the efflorescence might be due to some irritant of the vaso motor centres. It commences usually a few days after birth, and continues, in spite of every remedy yet tried, for twenty or thirty years.

Unna examined the morbid growths histologically in 1887, and found the brown coloration to be a deposit of fine granular melanotic pigment in the basal rete mucosa, and subepithelium of the cutis. The elevations, tubercles, and plaques were caused by oedematous swelling in the papillary bodies, but more particularly owing to the aggregation of Ehrlich's giant-cells in the papillæ. It has now been conclusively proved that these giant-cells are pathognomonic of the morbid process which is now presumed to depend on an angio-neurotic condition.

Ehrmann thought the presumption of irritation clinically failed in this case, as no irritation seems to have been present at any time of its history. He did not scruple to accept an angio-neurosis, but to his mind the symptoms did not justify an irritative origin. The giant-cells might be the product of some toxic influence and probably the real cause of the disease.

#### CHRONIC ENTERO-STENOSIS.

Ewald brought forward a child on whom he had operated for cicatricial stricture in the lower part of the jejunum. The central cicatrix was the result of tubercle. Above the stenosis there was great dilatation but very little hypertrophy, while below the bowel was empty and contracted. In the region of the ileo-cæcal valve a second stricture was present, which was resected also. The physical conditions were similar to the above, *i.e.*, above the stricture great dilatation was present, but no hypertrophy, which is usually present above obstructions. From these facts he attempted to evolve the principle that when we meet with an obstruction with dilation above and no hypertrophy, diligent search should be made for other obstructions in the bowel as in the case presented.

### Dungary.

[FROM OUR OWN CORRESPONDENT.]

BUDAPEST, December 24th, 1904.

#### HEART SYPHILIS.

In the current number of the *Gyógyászlat*, two cases of heart syphilis are described by Hartge:

CASE I.—A clerk, æt. 48, had suffered for several years from cardiac pain radiating down the arm, when he suddenly became unconscious and was apparently moribund. He was revived with stimulants, but suffered from attacks of excruciating pain for weeks, for which morphine injections were required. The cardiac physical signs were normal; the pulse was intermittent, but varied in frequency. As there was a history of a penile sore for which he had taken calomel internally thirty years previously, and of his wife having had several abortions, but no full-term children, he was treated with inunctions of blue ointment and iodides internally. Improvement was slow, but a year later he could resume his business, the pain had ceased, and the pulse scarcely varied in frequency; arterio-sclerosis could be excluded as there were no signs of it and the improvement was permanent.

CASE II.—A merchant, æt. 42, had syphilis at 22, for which he was most carefully treated. Ten years later he had cardiac pain radiating down the left arm, which, as there were no physical signs, was attributed to hypochondriasis. The patient, however, applied anti-syphilitic remedies and was cured. On two subsequent occasions this history was repeated. On the last occasion the symptoms, which consisted of a feeling of oppression, insomnia, constipation, and anginal attacks, for which morphine was required, did

not disappear till some months after a course of mercury and iodides. The patient is now quite well.

#### URTICARIA FROM ODOURS.

An unusual case which has defied treatment may here be recorded: A man, æt. 26, of a naturally intemperate and nervous temperament, presented himself at the clinic. Eleven years previously he had had adenoids in the naso-pharynx, which were cured by operation. He never could endure the perfume of eau de Cologne, musk, patchouli, and other toilet scents, and could not enter a barber's shop, as these odours always produced severe migraine. He became a liqueur manufacturer, and remained one day for two or three hours in the "laboratory." Headache, giddiness, and syncope ensued. On being removed he sneezed violently and was troubled with abundant nasal discharge. His face then swelled and the whole body was covered with an urticarial eruption accompanied by burning sensations and great itching. Similar symptoms followed other attempts to remain in the laboratory and appeared to be always provoked by the perfumes of aniseed, peppermint, fennel, coriander, and other aromatic substances. Examination of the nose showed nothing abnormal, except slight swelling over the right inferior turbinated bone. There was no hyperæsthesia. All treatment proved futile.

Dr. Hülth Hümér related cases of

#### SYPHILIS OF THE THYROID GLAND.

The cases fell into two groups:—

GROUP I.—Acute syphilis with enlargement of the thyroid (thyroiditis parenchymatosa syphilitica). There is a diffuse enlargement of the gland, due to acute parenchymatous inflammation such as occurs in the liver, spleen, &c.

GROUP II.—This group is found in congenital and tertiary syphilis. There are two varieties sharply distinguished from each other.

(a) Thyroiditis interstitialis syphilitica. Only two cases are on record. In one the syphilis caused myxœdema, which rapidly disappeared under anti-specific treatment. In the second a tumour, the size of the fist, was thought to be malignant. Complete excision was impossible. Microscopic examination revealed its benign character. The patient had acquired syphilis many years previously. Under treatment with potassium iodide, the tumour completely disappeared in three weeks.

(b) Gumma glandulæ thyroideæ. Several cases have been observed in children, the subjects of hereditary syphilis. The writer records a case of acquired syphilis. A man, æt. 58, had carcinoma of the larynx and benign tumour of the thyroid. Tracheotomy was performed on account of dyspnoea and cyanosis. To reach the trachea, the enlarged thyroid was divided with Paquelin's cautery. There was much hæmorrhage, and the patient developed acute bronchitis. After three months' treatment with potassium iodide, the enlargement entirely disappeared.

### The Operating Theatres.

#### NORTH-WEST LONDON HOSPITAL.

OPERATION FOR CHRONIC NASAL CATARRH OF ELEVEN YEARS' STANDING.—MR. MAYO COLLIER operated on a boy, æt. 15½, the subject of chronic nasal catarrh with snuffing and mouth-breathing for the last eleven years. The mother, who accompanied the boy to the hospital, stated that as long as she could remember her son had perpetual cold in the head, running from the nose, and cough, more especially at night and in the morning. In fine and dry weather, for a few weeks at a time, he was more or less free from cold in the head, but on the slightest provocation his nose became almost completely stopped up, necessitating the frequent use of a handkerchief. The boy complained of headaches and disinclination to follow his studies or to indulge in the ordinary games that most boys are pleased with. Mr.

Collier pointed out that at his first examination he was surprised to find, with a history such as had been related, that the arch of the teeth and the position of the palate were scarcely at all affected; as a matter of fact, the maxillary arch was particularly well formed and the teeth well shaped and well grown, and in perfect symmetry. The arch of the palate was an example of what an arch should be, and the whole of the upper jaw was well developed, and in keeping with the rest of the face. One would have expected, he said, that with a history of nasal obstruction for eleven years the maxillary arch would have been disarranged and the palate high and V-shaped. The more or less continuous nasal obstruction could only, he thought, have been of recent date, otherwise the palate and the whole upper jaw must have suffered severely. Mr. Collier further remarked that the state of the nose and of the posterior nasal space was typical of the condition of chronic nasal catarrh. The mucous membrane of the whole nasal cavity was hypertrophic and congested, and the lower turbinal bodies on both side were completely occluding the lower meatus. There was little doubt, he said, that the post-nasal space was full of adenoid vegetations, which would be easily inferred from the elevations present on the oro-pharynx. He proposed not only to remove the vegetations on the oro-pharynx, but also to take away the whole of the redundant tissue hanging from the lower border of the lower turbinal bodies. The patient having been anaesthetised with chloroform, Mr. Collier introduced a long straight pair of serrated forceps in each lower meatus, and with the assistance of his left index finger in the post-nasal space he engaged the whole of the redundant tissue in the grasp of the forceps; these, then, being securely locked, a few twists to the right and left were sufficient to remove the tissue in question. Very little bleeding followed this manoeuvre. The same operation was next repeated on the other side. The oro-pharynx was found to be full of adenoid vegetations, and these were removed with a curette. A good deal of hæmorrhage followed the removal of the adenoid vegetations, but the pressure of a sponge in the posterior space soon controlled it. The improved nasal respiration was very apparent during the bleeding from the posterior nasal space, blood and air passing through the nasal chambers with great ease. Mr. Collier said that any other treatment but the one adopted was, in his mind, quite futile in dealing with such cases.

**OPERATION FOR RECURRENT POLYPI.**—The same surgeon operated on a woman, æt. 45, who four years ago had presented herself with severe asthma and nasal obstruction. He, on that occasion, removed twenty-nine polypi with the effect that the asthma had completely subsided, and had not even returned with the recurrence of the polypi. Mr. Collier demonstrated some particularly large polypi invading the vestibule on each side. With the assistance of 20 per cent. solution of cocaine and adrenalin, nine of these were removed so as to restore respiration on each side. He pointed out that in these cases it was not advisable to prolong the sitting indefinitely as the removal of the lower polypi made room for others which would be visible at a subsequent examination. It was remarkable, he thought, in this case that, although the polyp had returned, the asthma had not. The most the patient complained of was a troublesome cough at night time and in the morning.

WEDNESDAY, DECEMBER 28, 1904.

**UNAVOIDABLE MISHAPS FOLLOWING OPERATION.**

THE immense impetus that the discoveries of general anaesthetics and antiseptic methods have given to surgical operations has doubtless enlarged the scope of the benefits derivable from medical science to a degree undreamt of by practitioners of the early part of last century, and without attempting to minimise the good that has accrued to humanity at large by early and more extensive operations, it is well to bear in mind that there are still certain *opprobria medicinarum*, or, more strictly, *opprobria chirurgiarum*, which have yet to be removed. So little risk now attends operations conducted *secundum artem*, that the surgeon, in a case presenting difficulty in diagnosis, does not hesitate to open the abdomen or cut down on a tumour, in order to solve the problem by direct inspection. Compound fractures, once the most dreaded class of injuries, are now regarded so light-heartedly that simple fractures, such as those of the patella and olecranon, are exposed and wired without anxiety, and almost every week fresh surgical procedures are planned and carried out for the relief of symptoms that are merely uncomfortable, and detract but little from the enjoyment of life. At the same time the light-heartedness with which the surgeon takes his scalpel in hand occasionally receives a rude shock, not so much from any want of skill or prescience on his part, as from the occurrence of some unlooked-for eventuality which he is at a loss to explain even when it has happened. Some of these regrettable calamities were dealt with by Richardson, of Boston, in a recent paper read before the American Surgical Association, and what is true of his country, where operative surgery has attained such a high degree of evolution, is unfortunately no less true of the same art in the British Isles. In the first place, he asks very pertinently, can septic

infection always be avoided? Theoretically, of course, it should be, but even in the modern temple of asepsis, which no hospital is content to be without, infection of deliberate wounds does occur, and though the surgeon very justly regards such an event as a reproach on his *technique*, it may be taken for granted that while man remains fallible, breakdowns of this character will continue to happen. Even though the conditions of operation be approximated as closely as possible to those of a bacteriological experiment, there are certain factors that cannot always be eliminated, and, granted that it is possible, and it is always possible by aerial contamination for germs to reach a wound, the injury to parts entailed by the operation, and the impaired vitality of the tissues from cachexia or ill-health, will at times determine a suppuration which will cause unpleasant surprise when the dressings are removed. As with suppuration, so with hæmorrhage. Modern instruments and resources are theoretically as capable of abolishing risk from hæmorrhage as asepticism is that from infection, but without reckoning these instances in which oversight or technical difficulties have allowed a vessel to pass unsecured, there is a proportion of cases in which as far as our present knowledge goes, post-operative hæmorrhage may be said to be inevitable. Richardson instances the tendency to hæmorrhage exhibited by jaundiced persons who come under operation for the relief of obstruction to the gall-ducts; three such cases he has had in which, the patient died from uncontrollable capillary hæmorrhage, besides one similar death in a case where at the time the operation was undertaken a biliary fistula existed, and there was no jaundice. Richardson always tries for some time before undertaking an operation on jaundiced patients to promote the coagulability of the blood by giving ox-gall, fruit-acids, and calcium chloride, but he has not found these means always efficacious, and he consequently writes down a certain number of deaths from hæmorrhage after gall-bladder operations as unavoidable. Then, too, with regard to the fortunately rare cases in which hysterectomy is followed by complete suppression of urine, there seems to be a proportion of instances in which no amount of foresight or care can obviate this risk. When the kidneys are diseased, the surgeon should take care to ascertain the fact before operating, as death in such cases is to be apprehended, or, at least, feared, but even when the kidneys are demonstrably healthy hysterectomy sometimes is followed by suppression of urine, and no adequate explanation is forthcoming *post-mortem*. But the most common cause of unavoidable death after operation, and the one that causes both surgeon and relatives the greatest shock, is pulmonary embolism, and this occurs always almost without preliminary signs of phlebitis. It is principally after extensive dissections in the female pelvis that phlebitis occurs, and then generally in the veins of the left lower limb. Unpleasant and irksome as this complication is,

happily it generally subsides without giving rise to untoward symptoms—that is, if the phlebitis is not septic. Richardson, in five thousand abdominal operations, has never seen a simple phlebitis with thrombosis give rise to a pulmonary embolism, but, on the other hand, he has had the chagrin, shared by other surgeons, of seeing a patient making a typically good recovery from a severe operation on the uterus or the appendages suddenly carried off by pulmonary embolism. Rare though these unavoidable cases of death after operation are, they have to be seriously weighed against the advantages likely to accrue before undertaking or advising any surgical procedure on a patient.

#### NUMBERING THE PEOPLE.

THE burden of the white man becomes a very real factor in life when we consider our imperial responsibilities. Our Empire covers some twelve millions of square miles, just one-fifth of the surface of the earth; and the forty-one and a half million people in the United Kingdom, with some few million white men in Canada, Australia and South Africa, are morally responsible for the well-being of over three hundred and thirty millions of coloured folk. The responsibility rests heavily upon the authorities, more especially those who are concerned in the matter of safeguarding public health and local administration. The Census of 1901 has revealed very many curious facts, and these have been made available for consideration and comparison by the recently published General Report of the Commissioners. It would appear that in England and Wales there were 36,444 men and 10,426 women employed in municipal, parish and other local or county administration. This shows a very considerable progressive increase, for in 1881 there were rather less than 18,000 men, and only a little over 3,000 women so employed. By 1891 these numbers had risen to 19,700 men and a little over 5,100 women. To this enumeration we must add 2,174 men and 6 women engaged upon the making and upkeep of roadways, as well as 50,300 men paviors and one woman. This last item shows a remarkable progress, for in 1881 there were only 15,097 men so engaged. In drainage and sanitary service there were 7,189 men and 1 woman, which compares only with 1,363 men in 1881. As scavengers and crossing-sweepers we find 8,478 men and 110 women, comparing with 2,694 men and 174 women in 1881. This is a goodly army engaged in the noble work of good government and sanitary improvement. It is well to know that in spite of the outcry of reactionaries the number in these services are still increasing, and by comparison this is notably the case as regards women. There is a laudable tendency to appoint more lady sanitary inspectors, and, considering the overcrowded condition of the slums, this is a very necessary provision. The Census returns confirm the statements of the Registrar-General as regards the prolongation of

life and the fall in the birth-rate; but this latter defect is righting itself, at all events so far as regards England and Wales, though Scotland, and especially Ireland, still lag behind. The disquieting fact of the increase in the number of mentally deficient is somewhat discounted when we realise that at all events part of this increase is due to difference of classification, and more particularly to the text of the wording of the Census schedules. Formerly, heads of families were requested to give returns of "lunatics" and "idiots." In 1901 this was softened to "mentally deficient," and there can be little room for doubt that this suavity of the words produced a nearer approach to the truth. Still, the fact remains that at the last Census 4,393 persons in England and Wales, 4,078 in Scotland, and 5,618 in Ireland for every million were mentally affected. This compares with 3,552 in England and Wales, 3,358 in Scotland, and 4,504 in Ireland at the Census of 1891. It is also notable that patients in asylums have vastly increased. Turning to another aspect of the population, we find that there was a large decrease in the number of blind. The fall being from 838 persons to 792 persons per million inhabitants. We may, as sanitarians, take credit for a large share in this decrease, for undoubtedly, cleanliness is one of the great preservatives against this calamity. There was also a decrease in the number of deaf and dumb, which may, although in a lesser degree, be attributed to improved health conditions. There is a lamentable state of affairs revealed as regards poverty. At the taking of the Census it was found that one in every 131 males, and one in every 190 females, were living in workhouses or infirmaries. This shows a general increase over 1891 of 5.5 per cent. The greater number of men is partly accounted for by the fact that husbands and sons, when dangerously ill, must, almost perforce, go into the infirmaries, but women, for various reasons, are more often nursed at home. It was found that the greater number of men were classed as general labourers; they formed rather more than one-fifth of the total male population. As regards women, the most numerous class were domestic servants, who composed nearly one-fifth of the female workhouse population. Turning to yet another aspect of the returns, we find in some of the industrial centres an increase in the employment of very young boys, and a decrease in the employment of men above middle age; it would seem almost as if we had here some explanation of the growing pauperisation. A more pleasing fact is that, while there is an increase in the percentage of young women workers, there is a slight decrease in those employed about marriageable ages. This is a step in the right direction. We must leave for a future occasion the consideration of that most difficult of problems, the concentration of the population.

#### CONSUMPTIVES IN HOSPITALS.

THE question is rapidly coming to the front whether it is fair to the inmates of general hospitals

to expose them to possible tuberculous infection by allowing patients suffering from pulmonary tuberculosis to occupy the same wards as those suffering from other diseases. The fact that rooms, clothing, &c., can be, and are, rendered infective by prolonged contact with consumptives no longer needs demonstration, and already many municipal authorities have taken steps to secure the adequate disinfection of such premises, the destruction of clothing, &c. If it be admittedly dangerous for the healthy to inhabit rooms in common with the phthisical, how much more dangerous must it be for the sick in hospital? Their suffering bodies are obviously in a state of morbid receptivity, or, in other words, of diminished resistance, and it is impossible to deny that the presence of, it may be, a large proportion of tuberculous patients in the wards must create a very real danger for them. That the risk should hitherto have escaped practical recognition is due, no doubt, to the fact that the consequence does not follow so closely on the cause as to strike the attention, but in the light of our present knowledge the reality of the danger cannot much longer be ignored. If this argument should hold good for the inmates of general hospitals, how much more cogent is it in respect of hospitals which receive consumptive patients exclusively? There the infection is intensified, and they turn, so to speak, in a vicious circle. We refer, of course, to "closed" hospitals, for if certain precautions are enforced, the open-air sanatoria do not participate in this reproach. It is hardly to our credit that the initiative in the direction of the segregation, or shall we say the isolation of patients afflicted with pulmonary tuberculosis should have come from France. Yet such is the case, for we read that the Extra-Parliamentary Commission appointed some time since to consider how best to circumscribe the ravages of this disease, has rendered a report on the strength of which the Minister has drawn up a circular to be sent to all hospitals and similar institutions throughout the country, urging the desirability of taking immediate steps for separating tuberculous from non-tuberculous patients. The wisdom of such a course is so obvious as to dispense with the necessity for arguments to support it. We are aware that many diseases constitute a "soil of predilection" for infection by the tubercle bacillus, and we may go a step further and assert that every debilitating disease—and which of them is not debilitating?—creates a passing liability to tuberculous infection. Chronic malnutrition, however induced, as in diabetes, rheumatism, &c., materially reduces the vital resistance of the tissues, especially to tuberculosis. Yet we continue to permit a morbid promiscuity not so far removed from that of the days when three or four different patients were huddled into one hospital bed. We have separated the beds, but we have only reduced the evil in degree and not in kind. In years to come our successors will doubtless look with as much amazement on our present hospital promis-

cuity as we do on that of our predecessors. The erection of sanatoria is one step in the specialisation of hospitals from this point of view, but as the accommodation is unlikely, for many years to come, to suffice for more than an infinitesimal fraction of the tuberculous, it behoves us to provide provisional protection to the tuberculous sick unable to avail themselves of the advantages of the sanatorium. When we consider that in France 45 per cent. of the in-patients are tuberculous, it is evident that the problem is of some magnitude. One solution of the problem in town where there are several hospitals would be to allocate one or more of the buildings exclusively for this purpose. But patients evince the greatest objection to remain in such special institutions, preferring the general wards; moreover, the physicians attached to the particular hospital would probably object to the monotony of ministering exclusively to the phthisical. On the whole, the best plan for the present would seem to be to place apart certain wards in all hospitals for the reception of the tuberculous pending arrangements for relegating them to cheap buildings in the open air, far away from towns—a disposition which has the advantage of being as beneficial for the sufferers as it is hygienically desirable.

### Notes on Current Topics.

#### Toilette Eye Drops.

ANYTHING which is supposed to add to feminine charms is laid under contribution in these days, quite regardless of the consequences and risks. Perhaps one of the most reprehensible and dangerous practices in connection therewith is that which makes the delicate organ, the human eye, the medium for gratifying vanity. The following characteristic paragraph appeared in a recent number of a woman's magazine:—"A perfectly safe and successful way to secure the beauty of eyes that sparkle is to put a drop of '——' eye drops (price 5s. 6d. a bottle) into each eye before going to a dinner, a dance, or any other function, and then to take the bottle with one, and to put a drop with the finger-tip into each corner of both eyes when in the cloak-room. This will keep them bright the whole evening." We can only describe the advice here given as in the highest degree worthy of unqualified condemnation. To tamper with the eyes by applying to them drugs which are supposed to make these delicate organs sparkling and bright is, we imagine, a practice which would hardly appeal to persons of ordinary common sense. And yet it is grievous to have to admit that there are persons who, for the time being, cease to act sanely in order to pander to the demands of vanity. Vanity, as we know, stops at nothing; among some women it becomes a fetish, which dominates their whole being, and leads them into paths of foolishness and wrongdoing, escape from which is generally impossible without the payment of penalties—more or less severe. So far, however, as the promiscuous application of powerful drugs in the form of drops to

the eyes are concerned, every medical man knows that such a practice is fraught with the gravest risk to these organs, and the public should take warning that harm may result which cannot afterwards be rectified.

#### Influenza Rampant.

THE war clouds in the Far East are having a faint but distinctly undesirable reflex in the Far West in the shape of a widespread epidemic of influenza. It may be doubted whether the malady has ever been marked with a more rampant aggressiveness than that displayed during the past five or six weeks. Fortunately the type of the disease is mild, and many persons may be seen following their daily occupation with the dullness of this most depressing disease writ large upon their features. Needless to say, any patient who goes about his ordinary business while suffering from influenza is running a great and, it may be, fatal risk. Rest in bed, a dose of quinine, nutritious food and free stimulation are the best remedies, as all practitioners and most laymen have by this time learnt to recognise. For all the comparative mildness of the present type, influenza is, nevertheless, answerable for a great number of deaths in the United Kingdom. When the long-continued wave of infection shall have once again receded from our shores, it will be found that the total mortality has been little short of that experienced in a great national war. For all that, medical science may rest serenely happy in the firm persuasion that one day this preventable disease will be prevented. The influenza bacillus is doomed to share the fate of the mammoth and the dodo and other extinct animals.

#### A Novel Test for Sobriety.

MEDICAL men generally, and police surgeons in particular, are frequently called upon to give an opinion on the sobriety of an individual, and they know well that there is nothing a clever counsel can make more fun of, or discredit more easily, than evidence as to drunkenness. Unless a man was in an advanced stage of alcoholic poisoning, it is always possible for him to plead afterwards that he was ill, or mentally distracted, or under the influence of some other drug than alcohol, and—although the doctor may be perfectly certain in his own mind that drink was the cause of the trouble, it is very difficult to make the evidence sound convincing to an unsympathetic court. He may have applied the time-worn tests of "British constitution" and "mixed biscuits" and satisfied himself that the failure of the prisoner to tackle these "tongue-twisters" was the result of incoordination of the vocal muscles, but a lenient bench do not always find these tests conclusive. A novel and interesting experiment was introduced by Dr. Rigby into the examination of an accused man at Chorley the other day. Dr. Rigby had run through the gamut of ordeals for drunkenness without arriving at a result satisfactory to his own mind, although the prisoner was able to carry a full glass of water across the room and back

without spilling more than a few drops at the turn. The policeman was sure the man was drunk from "the gleam in his eye," so Dr. Rigby evolved a final and extempore test by making the accused read a copy of the Education Act. He accomplished this task with such a command of phrase, and such a degree of scholarship, that the magistrates' hearts melted when they heard of it, and they accepted the prisoner's view of his own case. The Education Act has been the cause of much vituperation and has had many unkind things said about it, but if it can ward off convictions for drunkenness it is likely to be cherished in a good many homes.

#### The Conferring of Honorary Degrees on Sir F. Treves and Major Ronald Ross.

THE Senate of Dublin University, at its last meeting conferred the honorary degrees of Master of Surgery and Doctor of Medicine on Sir Frederick Treves, C.B., Surgeon-in-Ordinary to the King, and of Doctor in Science on Major Ronald Ross. The Public Orator was most happy in the Latin speeches in which he introduced the recipients of the degrees. "To Sir Frederick Treves principally, as Serjeant Surgeon-in-Ordinary to the King, is attendance on his Majesty entrusted, as, of old, attendance on the Emperor Augustus was assigned to Antonius Musa. You all remember the gratitude and uplifting of heart with which not only we, the subjects of his Most Gracious Majesty, but almost the whole world, rejoiced at the happy result of this eminent surgeon's skill, when the head and main pillar of the State was endangered, and it was uncertain whether that august brow was to wear the covering of death or the royal crown. Formerly, too, in the South African war, this great surgeon had shown with marked success his beneficent and salutary skill." The reference to Major Ross was no less happy, and ran as follows:—"The serious mortality caused by those minute yet deadly parasites, called plasmodia by scientific men, is well known; nor can any more righteous war be waged than that against those microscopic Hydras which germinate in their myriads throughout our frame. In this war a most brilliant victory has been gained by Ronald Ross, a man of the most varied and striking gifts. Formerly a distinguished major in the Indian Medical Service, he has also won success as a profound mathematician, an admirable novelist, a dramatist of no mean order, and now is one of the most eminent of Professors in Tropical Medicine. It has been supposed that malaria arose, as Lucretius says:—

When soaked with drenching rains the wide  
earth streams,  
Corruption breeding 'neath the sun's fierce  
beams.

But, entering on a new and unerring path of investigation, this great man has shown with brilliancy and certainty that the seeds of that disease are carried broadcast by mosquitoes, so that in numberless cases whomsoever those noxious creatures bite, they not merely bite, but infect with

poison. And so it has come to pass that by his aid we can clearly learn in what way to avoid this most grievous malady." The University is to be congratulated on the choice of the two eminent members of the medical profession whom it has selected for honour.

#### "Harvey Lewis," Memorial Hospital.

ACCORDING to our lay contemporaries, the sum of £80,000 has been recently left by a charitable devisor for the ultimate purpose of founding another hospital in Dublin. While we quite recognise that such a munificent bequest for charitable purposes is worthy of the highest praise, we are compelled to express our regret that the devisor was not better advised. We believe that our readers will agree that while one of the chief needs of Dublin in the direction of charity is the provision of greater funds for the existing hospitals, the last thing required is the creation of a new hospital. To put the present state of affairs concisely, buildings are plentiful, but annual income is small. If in the present case this magnificent sum had been apportioned between the large Dublin hospitals, the benefit would have been incalculable. As it is at present apportioned, it merely means that an insufficient sum will be spent in unnecessary bricks and mortar, and that another hospital will be created to vie with those at present existing in appeals to the charitable.

#### The Sugaring of Wine.

ALL that glitters is not gold, and not all so-called wines are the fermented juice of the crushed grape. It is easy and economical to manufacture a palatable liquid from dried raisins which, in skilled hands, closely approximates real wine in appearance and taste. During the last few years however, the production of wine, particularly in Algeria, has been so abundant that it has hardly been worth while to employ the comparatively expensive raisins, but wine-growers in France are up in arms against another form of sophistication which interests us as consumers. This consists in the employment of sugar, either to reinforce wines that are deficient in alcoholic strength, or for the purpose of "making" wine by pouring water on the residues after the expression of the true wine; this, duly fortified with sugar, is allowed to ferment, and so the unscrupulous grower gets a second drop, so to speak. From the point of view of health, the practice is probably attended by little risk in spite of the specious arguments advanced by those who desire to see it put a stop to. But it is none the less a distinct fraud on the public, and what is more to the point, the revenue in France is thereby defrauded of its due, since the additional alcohol thus added to the wine escapes taxation. Wine is so plentiful in many parts that it is sold at three halfpence a quart, and the market is glutted even at this price. One can understand, therefore, that wine-growers resent unscrupulous dealers being allowed to enhance the existing

stagnation by artificial means, and as they are an influential body we are justified in hoping that all the wine imported to England will, in the near future, be the unsophisticated juice of the grape.

#### Medical Report on the Boer War.

THE quality which is designated in parliamentary circles "indecent haste" certainly has not characterised the publication of the medical report on the South African war, for it only put in an appearance last week, and even now it is far from complete. The task of preparing it has truly been a herculean one, and it cannot be said that Surgeon-General Sir William Wilson and his staff have shirked their work. Still it is not unreasonable to suppose that with a little organisation and equipment the report might have been issued some considerable time back, and we suppose that the fixed military principle of cutting the Medical Department down to the severest limits lies at the root of the long-drawn-out delay. Coming as it does years after popular interest in the events of the war and the popular indignation at the breakdown of the medical arrangements have subsided, we fear that it will do little to clear the *personnel* of the medical staff from the blame so freely attached to them at the time; but if people will take the trouble to read the report now that it is published, they will find that, whoever was to blame, it was not the Director-General and his colleagues. Medical men who are acquainted with the scandalous shortage of officers in the Royal Army Medical Corps long before the war broke out had over and over again predicted a catastrophe when the strain of active service was experienced, and it is only fair to say that the predictions were nullified solely by the unceasing devotion to duty of the army doctors themselves. But although an actual catastrophe was avoided, a very serious breakdown occurred, and how it all came about may now be read in the official report. The one bright spot that shines all through the Blue Book is the fact that under conditions of storm and stress the officers and men of the Royal Army Medical Corps acted up to the highest traditions of a service whose motto is self-sacrifice, and whose reward principally consists in the possession of the *mens conscia recti*.

#### Neurasthenia.

It is not often that a man assumes in public the rôle of iconoclast of the images made by his own hands. Yet this seems to be the position of Dr. Charles Dana in regard to the disease "neurasthenia," which owed its name and its recognition as a clinical entity to him in association with Dr. Beard. In a paper recently read before a New York audience (a) he declares that the word has become so misapplied that in the near future it is bound to disappear from the terminology of accurate diagnosis. At the time of its introduction the word gave greater definiteness to a group of clinical phenomena which had formerly been referred to

under the vaguest terms—"the vapours," "hypochondria," "the spleen," "liver troubles," and so on. Nowadays, however, it only serves to cloak diseases and conditions which deserve distinctive names, and it causes confusion by grouping together neuroses and psychoses. Indeed, according to Dana, the great majority of the cases passing under the name "neurasthenia" are psychoses of one sort or another, being most commonly mild forms of melancholia. For instance, the "queerness" of young persons who lose interest in their work and in the things in which their fellows are accustomed to be interested has commonly been described as "neurasthenia," whereas it is in reality a form of the insanity of adolescence. On the other hand, there are some conditions of purely physical and non-nervous origin which have been confused with neurasthenia. For instance, the "status lymphaticus" of young people gives rise to a phlegmatic condition which has often been mistaken for it, and in the old a lethargy, the result of arterio-sclerosis, has caused similar error. The word "neurasthenia," according to one of its authors, has fulfilled its function in the development of knowledge, and may be allowed to disappear.

#### Draughts in Railway Carriages.

FASHIONABLE and healthy as is the desire for fresh air, there is one form of fresh air which medical science is not required to inform people is injurious, for it is abundantly obvious to every man of common sense. We mean draughts. The chilling of one area of the body whilst the rest of the surface retains its normal heat is not only uncomfortable, but dangerous. Such chills usually affect the head and neck, because, being uncovered, they are most exposed to the influence of draughts and currents of cold air. Among minor ills thus produced, tooth-ache, neuralgia and torticollis are perhaps the commonest, but facial paralysis, which may even remain permanent, is not infrequently seen in those who have fallen asleep with cold air playing on one side of the face. Of all places the one in which it is most difficult to avoid draughts is the railway carriage, and though comfort in travelling has greatly increased during the last few years, but little has been done to make the average railway-carriage a place where pure air can be breathed without draughts being created. The northern railway companies have improved on the old hot water-tin as a carriage warmer, but the steam-heated carriage is nearly always stuffy, and the southern lines, for the most part, have taken little trouble with regard to either warming or ventilation. A correspondent of the *Times* suggests a method of keeping the rush of air created by the train from entering the carriage of such simplicity that we wonder it has not been tried long before. It consists in placing a board four inches in width to project wing-wise outside and in front of the carriage windows. The correspondent alluded to claims that by this means the carriage-windows

(a) *Medical News*, October 8th, 1904.

can be opened to any desired degree without any draught being felt by the passengers. We have not tried the experiment ourselves, but it sounds perfectly reasonable in principle, and if it is as effective in practice as it seems likely to be the railway companies should surely have no excuse for not adopting it. A long railway journey in the cold season of the year, especially to people not accustomed to travelling, is a severe menace to health, and it is little less than monstrous that this should be so at the present day.

#### Scientific Research at Khartoum.

To those who are interested in the study of tropical medicine, the report of the Wellcome Research Laboratories at Khartoum will be of particular value. It will be remembered that at the time of the establishment of the Gordon Memorial College, Mr. H. S. Wellcome, of London, fitted these laboratories and presented them to the Soudan Government. The work of carrying them on was entrusted to Dr. Balfour, as director, and the first report has recently been issued. Though Dr. Balfour has no skilled assistance provided in the laboratories, he seems to have the gift of obtaining it from his friends, and much valuable work is being done by medical and veterinary officers in the service of the Soudan Government, as well as by military medical officers stationed at Khartoum. All this work centres round the Wellcome Laboratories, and is, as it were, inspired by the director. Dr. Balfour's own work seems to be very wide, for up to the present he has rather been making acquaintance with the general facts of epidemiology in the Soudan than devoting himself to any particular line of investigation. Malaria is commoner at Khartoum than is generally supposed, and soon after Dr. Balfour's arrival an anti-malarial brigade was organised on Major Ross' lines with very gratifying results. It is noticeable that, in spite of the dry, hot climate, tuberculosis is common among the natives, but, as its incidence is greatest on women and children, it is almost certainly due to the dark, close, crowded huts they inhabit. Syphilis of very severe type is prevalent, and as among the natives it is considered rather an honour to have the disease, no steps are taken to counteract it. The Director and his friends are engaged in collecting and examining blood films from all sorts of cases of tropical disease, as well as in systematic bacterioscopic work. There is no doubt that the establishment of an institution such as that at Khartoum will lead to advances in tropical medicine which would not otherwise be made.

#### Copper as a Bactericide.

THE purification of water is admittedly one of the problems of the day, for whatever care is expended in the collection of water, the inspection of sources, and filtration, a proportion of water-borne disease persists in most large towns. Although there are more agencies than one by which typhoid may be disseminated, water is still the chief, and typhoid fever continues to occur in the

autumn with a regularity which indicates that a good deal remains to be done in the treatment of water before it reaches the consumer. What the eventual method may be, it is impossible to say, but that in the future sterilised water will be considered the only safe water for people to drink admits of but little doubt. A plan for treating water on a large scale at a nominal cost has been suggested by Dr. Moore, who has carried out experiments to attain his object, and who is convinced that he can render water free from algæ and bacteria by means of his method. This consists in adding to the water it is wished to purify, copper sulphate in the proportion of 1 to 100,000, which he claims is sufficient to kill virulent colonies of typhoid and cholera in four or five hours in water at ordinary summer temperature. We confess to feeling some surprise that so weak a solution can be efficacious, but even if it is there remains the objection that the consumers of the water would have to imbibe a certain amount of copper with the fluid. A great deal of discrepancy is still to be found among authorities as to the toxic powers of copper, but it cannot but be a big experiment to make people drink minute quantities of it in solution every day of their lives. It is claimed that less copper is contained in a gallon of water so treated than in an ordinary loaf of bread or cake of chocolate, and that therefore the amount of copper is harmless to effect any pathological changes. However this may be, purifying water by the addition of chemicals that must eventually reach the tissues of the consumers is an experiment not to be lightly tried, and it certainly is not the final solution to the problem of water sterilisation.

#### Gentleness in Manipulation.

THE importance of being extremely gentle in diagnostic manipulation was recently brought before the profession in America in a discussion (a) opened by Dr. Howard Kelly, of Baltimore, who made special reference to injuries sustained by the bowel in the course of gynecological examinations. Many other instances were enumerated, however, of the damage that may be done by the slightest roughness in performing abdominal palpation. For instance, in the experience of many of the speakers, and probably of many of our readers, such accidents have occurred as the rupture of a thin-walled cyst, or, still worse, of a localised abscess. Even the rupture of a tubal pregnancy is reported to have taken place from the energetic examination made by the relative of a patient to satisfy himself of the correctness of the diagnosis of an attending physician. The perforation of the uterus by a sound is so common an accident as to need no special mention. The accident of perforation of the rectum by the examining finger is less common, but, nevertheless, Dr. Kelly has seen it happen four times. The principal predisposing condition is a loss of muscular tone, usually occurring in elderly, flabby women. In such patients a rectal examination should be made with great

(a) *Journ. Amer. Med. Assoc.*, November 26th, 1904.

care and deliberation. The best treatment, if the accident should occur, is immediate opening of the peritoneum, preferably by the vaginal route, and suture of the rent from the peritoneal aspect.

#### Tattooing and Disease.

THE natural instinct for personal adornment, like many other primitive impulses, still survives in the present day, even among the male sex, who, if they cannot render their clothing attractive, seek to enhance their cutaneous charms by imprinting various devices and patterns upon their epidermis. As a matter of fact, it is the true skin which has the greater share in bearing the permanent decoration, for it is well known that the durability of the marks depends entirely upon the depth of the punctures. The practice of tattooing is of great antiquity, and many different substances, such as clay or pine-resin, have been introduced by native tribes beneath the skin, the use of indigo or vermilion following at a somewhat later period. The desire for early recognition and identification after death would seem to be one reason for the great popularity of tattooing among soldiers and sailors. On the other hand, many distinguished personages are thus branded with mystic emblems from wholly different motives. In the annual report of the Director-General of the Medical Department of the Navy, recently issued to the Admiralty, an interesting paper may be found by Staff-Surgeon Finch, of H.M.S. *Thetis*, which deals with the subject of the communication of disease by tattooing. In 1878, Maury and Dulles reported a series of fifteen cases in which syphilis was definitely communicated through the practice, the virus having effected an entrance into the tattooed individuals through the needles which were moistened by the lips of the operator, who was himself the subject of the disease. In these patients there had never been any pre-existing venereal affections. A further series of twelve cases was described by Surgeon F. R. Barker, in 1889, in which an outbreak of syphilis was distinctly traced to the practice. Unless the strictest aseptic precautions are observed, it is obvious that many other contagious or microbic disorders might be transmitted by any operation, however trivial, involving a puncture of the skin.

#### Steedman's Powders.

A CASE of some interest, both to medical men and chemists, was decided at the Coroner's Court, Hammersmith, last week. It appears that a child, eight weeks old, was given a Steedman's powder for the relief of pain, and twenty and a half hours later died, the symptoms being contraction of the pupils and sleep. Dr. William Robert Hall Hains, who saw the patient during life and also made the autopsy, was of opinion that death was not due to natural causes, but was accelerated by some narcotic poison. Suspicion naturally fell on the powder, and the matter was referred by the Coroner to Dr. Freyberger for report. At the adjourned inquest it was definitely stated by the proprietors

that although the composition of the powder was a trade secret, it contained neither opium nor morphine, and was free from any toxic agent. Dr. Freyberger said that he had examined not only the viscera and the contents of the stomach, but the remains of the powders, and found that they were absolutely free from any trace of opium or any narcotic substance. Dr. Wilson Hake, of the Westminster Hospital, said that he had purchased samples from various sources, and had also examined the manufacturer's stock and was unable to find narcotic acid or any opium alkaloid. Dr. Murrell stated that neither the symptoms nor the *post-mortem* appearances were indicative of opium poisoning, and that in all probability the child had died either from broncho-pneumonia or congestion of the brain. Dr. Hains, on being recalled, said that after hearing the expert evidence he was perfectly satisfied that death was due to natural causes. He asked if he had been right in refusing a death certificate. The Coroner, in reply, said that the Court was much indebted to Dr. Hains, and that he had acted very properly in the matter. A verdict in accordance with the medical evidence was returned. As the sale of these powders is said to amount to many millions in the year, this result is of some public importance, however much as a scientific profession we may and must condemn the use of nostrums under such a misleading and unscientific name.

#### The Corset Again.

THERE is no more ruthless exposé of woman's follies than the woman who has emancipated herself from their thralldom, and Miss Arabella Kenealy goes for her weaker sisters to some purpose in "The Nineteenth Century and After" this month. The bone of contention is the bone of the whale, and the way that the female of human species surrenders herself to its embrace. It hardly needs a medical expert to point out that compressing the viscera in an iron grip, so that they are distorted in shape and displaced in position, is not calculated to aid them in the performing of their physiological functions. Such a truism the silly creatures who practise the art of tight-lacing would simperingly admit themselves. What would give its quietus to the production of this artificial deformity would be the pencil of the caricaturist and the pen of the satirist, who laughed the crinoline off the stage. In the meantime, the vigorous onslaughts of Miss Kenealy are all to the good, and some of the facts certainly are not generally known. It may be news to many readers to hear that a series of experiments were made some years ago on monkeys, to study the effects of tight-lacing. The poor creatures were encased in fashionable corsets and then squeezed till their figures approximated as closely to the "wasp" type as the simian waist can approach. It is not stated under what schedule these experiments were performed, and no mention is made of anæsthetics. In spite of a natural presumption to the contrary, the ape of the woods did not show

himself possessed of the constitution of the *grande dame* of Belgravia, for some only lived a few days in their Parisian habiliments. The others lingered for months in agony, and died of disorders produced by the stays. One important—nay, vital point was overlooked by the experimenter. He was thinking so much of the duration of the monkeys' agony—which, of course, was only an incidental question—that he forget to observe if the male monkeys exhibited a more decided *penchant* for the embrace of the corseted ones than they usually do for their naked, but unashamed, colleagues. It is to be hoped that the experiments will be repeated with a view to unravelling this crucial problem.

#### Symbiosis among Bacteria.

THERE are few more enticing studies in the field of biology than that afforded by the subject of symbiosis, and few paths which lead one into more unexpected regions. Thus, for example, the classic instance of the connection between the life of certain wild bees and the presence of the domestic cat is, at first sight, quite inexplicable, yet the causal relation is simple enough. The bees are unable to cope with a large population of field mice, and the great check on the latter is the domestic cat. In the realm of bacteriology there is good reason to believe that certain instances of [symbiosis occur which are of practical importance, and the suggestions on this subject made by Dr. Klein, in his recent Dobell Lecture, open up a promising field of research. It is known, for instance, that in many cases the lesions due to a mixed infection are greater than would result from a pure infection by any one of the organisms concerned. Sometimes an infection by one organism may be causing but little damage, when the addition of another excites a startling increase of injurious processes. This occurs, for instance, when a streptococcal infection is superadded to that of the diphtheria bacillus. In such cases Dr. Klein suggests that not merely does one organism serve to prepare the ground for another, but that one in some peculiar way actually increases the virulence of the other. Similarly it is possible and probable that a tuberculous focus receives an impetus to spread from a secondary infection of different kind, and that the secondary infection directly increases the virulence of the tubercle bacillus. The difference between active and resting foci of tuberculous disease may, on this theory, be explained as due to the presence or absence of a second infection.

#### Hospital Museums.

THAT the proper study of disease is incomplete without a knowledge of the pathological changes and appearances that occur in the organs and tissues affected few will be found to deny. There are some who aver that too much time may be spent over test-tubes and microscopes, and, to some extent, there is a danger lest the office of the bacteriologist or the chemical physiologist be un-

duly magnified. It is in the dead-house, however, that the closest acquaintance is made with actual disease-processes, and the practitioner who is most familiar with morbid pathology is in a far better position to tackle a difficult case than the casual visitor to the *post-mortem* room. What medical man has not experienced the peculiar thrill, akin to awe and reverence, excited by a typical specimen of some strangely altered organ seen or handled for the first time? It is the contemplation of such a departure from the normal which fills the studious onlooker with a deeper desire to find out the reason why such things befall the human body. His enthusiasm is stirred, and if he possess any fraction of the spirit of scientific research he will not rest until he has thoroughly grasped the nature of the disease in question. It is the most natural thing in the world, therefore, that the clinical museum should be not the least important part of the modern hospital equipment, more especially if there be a medical school or post-graduate college attached to the institution. Professor Thomas McCrae, of New York, is impressed by the fact that, taken all round, the hospital museums in this country are accessible to students and are really utilised as places of study. This is certainly the case as far as the great centres of medical education are concerned, but we fear that even now in some of the smaller hospitals the museum is conspicuous by its absence, or is relegated by the governing body to the worst and most badly-lighted quarters of the building. It sometimes happens that good specimens are lost or thrown away by practitioners simply because the nearest hospital to them has no museum. There is certainly room for more enterprise on the part of hospital authorities in this direction.

#### PERSONAL.

HIS MAJESTY THE KING has graciously been pleased to grant the title "Royal" to the Victoria Hospital for Consumption, Edinburgh.

A DINNER, given on December 11th, to Professor Koch to celebrate the sixtieth anniversary of his birthday was attended by a great many of his former assistants, including Professor Brieger, Professor Löffler, Professor Gärtner, and others. All the members of the Institution for Infectious Diseases were present.

LORD STRATHCONA and MOUNT ROYAL will preside at a festival dinner to be held at the Whitehall Rooms, Hotel Metropole, London, S.W., in aid of the National Hospital for the Paralysed and Epileptic on April 12th next.

THE foundation stone of the Llanybytheris Sanatorium for consumptives for the counties of Cardigan, Carmarthen, and Pembroke, is to be laid on April 26th, 1905, by Princess Christian.

DR. E. S. STOKES has been appointed medical officer and bacteriologist to the Metropolitan Board of Water-supply and Sewage, Sydney.

MR. EDWARD TURNER BORN, M.B. Dunelm, J.P., has been promoted from Assistant Colonial Surgeon, Fox Bay, West Falklands, to the Hon. the Colonial

Surgeon, Stanley, East Falklands, President Board of Health, and Member Executive and Legislative Councils

MR. T. CRISP ENGLISH, B.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to St. George's Hospital and Lecturer on Operative Surgery, St. George's Hospital Medical School.

DR. A. P. LUFF has been appointed Physician to the In-patients at St. Mary's Hospital.

ON the 15th instant, Miss Amy Sawyer, third daughter of Sir James and Lady Sawyer, of Birmingham, was married to Mr. H. H. French, of Guy's Hospital.

DR. WALTER SMITH, King's Professor of Materia Medica and Pharmacy in School of Physic, Trinity College, Dublin, has been appointed to examine at Examinations of Army Medical Service.

DR. J. MAGEE FINNY, ex-president R.C.P.I., has been appointed Honorary Consulting Physician to the Royal Hospital for Incurables, Donnybrook, Dublin, in place of the late Dr. John J. Cranny.

COLONEL (temporary Surgeon-General) W. F. Stevenson, M.B., C.B., Royal Army Medical Corps, Professor of Clinical and Military Surgery, Royal Army Medical College, has been appointed an Honorary Surgeon to the King, *vice* Surgeon-General J. Jameson, M.D., C.B., deceased.

THE President of the Board of Education has appointed Dr. Norman Moore, M.D., F.R.C.P., to be a member of the Consultative Committee, *vice* Professor Bertram C. A. Windle, M.D., F.R.S., resigned upon appointment as President of Queen's College, Cork.

### Obituary.

ARTHUR QUARRY SILCOCK, M.D. LOND., B.Sc., F.R.C.S.

WE regret to announce the death of Mr. Arthur Quarry Silcock, the eminent surgeon and ophthalmologist, which occurred on the 19th instant, after a short illness, at his residence, 52, Harley Street, at the premature age of 49. Born at Chippenham, Wiltshire in 1855, he was educated privately at University College, London, taking the B.Sc. degree at London University in 1878, and being admitted the same year as a member of the Royal College of Surgeons, England. In 1880 he proceeded to the M.D. degree, and in 1882 was elected a Fellow of the Royal College of Surgeons. Dr. Silcock, in the course of a successful professional career, filled many important positions. He held the post of senior demonstrator of anatomy and demonstrator of practical surgery at University College Hospital, where he was also surgical registrar, house physician, and house surgeon. He was pathologist and lecturer on practical and operative surgery and pathology at St. Mary's Hospital, and had also been president of the University College Medical Society. At the time of his death he held the offices of surgeon and joint lecturer on surgery at St. Mary's Hospital, surgeon to the Royal London Ophthalmic Hospital, consulting surgeon to the Bromley Cottage Hospital, and examiner in surgery for the Royal College of Surgeons. Dr. Silcock was a Fellow of the Royal Medical and Chirurgical Society, and a member of the Ophthalmic, Clinical, Pathological, and Harveian Societies. He was the author of "Injuries of the Eye" in "Druitt's Surgeon's Vade-Mecum" and had contributed a large number of papers to the transactions of the Pathological, Clinical, and Ophthalmic Societies, as well as many articles to the professional journals.

GEORGE ANDREW CAMPBELL, M.D. Ed., R.N. DEPUTY Inspector-General of Hospitals and Fleets

George Andrew Campbell, M.D., R.N. (retired), of 2, St. Leonard's Road, Ealing, whose death on the 19th instant, at the age of 68, is announced, was educated at Harvard, U.S.A., and at Kingston, Canada, where he took his M.D. degree in 1859. Entering the Navy in 1860, he became a staff-surgeon in 1872, and in that rank served in the *Hecle* at the bombardment of Alexandria, on July 11th, 1882, during the Egyptian campaign which followed, and throughout the naval and military operations near Suakin, in the Eastern Soudan, in 1884. For his war services he received the Egyptian Medal, with the Alexandria and Suakin clasps, and the Khedive's bronze star. He was promoted to the rank of fleet-surgeon in 1883, and retired in 1891 as a deputy-inspector-general.

CHARLES FREDERICK LAING, M.D.

THE death took place at sea, near Gibraltar, on Tuesday week, of Dr. Charles F. Laing, medical superintendent of Somerset and Bath County Asylum. A few days ago Dr. Laing started on a voyage for his health, and he was on his way to Egypt when the sad occurrence took place. Dr. Laing, who was only in his 36th year, was born at Paisley. He was a son of the late Mr. Charles W. Laing, governor of the Town's Hospital, Glasgow, and was educated at the High School and Allan Glen's School, and afterwards at Glasgow University, where he graduated M.B., C.M. in 1890. A year later he received an appointment at Smithston Asylum, Greenock, and from there went to Cheshire County Asylum at Macclesfield as assistant. Three years ago he was selected from a large number of applicants as superintendent of the important county asylum at Wells. Dr. Laing was well known in Glasgow. By his death a career full of promise has been prematurely closed.

### Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

HOSPITAL FUNDS AND SMALL HOSPITALS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Hospitals exist primarily for the relief of the suffering poor; they are further needed to provide clinical material for the education of students of medicine, and they furnish a field for the scientific observation and study of disease and pathological phenomena. Hospitals do not, or at least should not, exist for the purpose of enabling a few practitioners to get on in the world; but this seems to be the idea of some correspondents who so far have taken notice of my letters. This latter is, in fact, the purpose for which most existing special hospitals were founded, and for which some of them are being still employed. This no doubt suits some individuals; but it is very bad for the bulk of the profession. The whole special hospital system is associated with other evils, some of which I have previously referred to, and it is the cause of waste of public funds which, if applied to legitimate ends, would serve almost alone to satisfy the needs of great institutions which in every essential respect are beyond criticism.

I am, Sir, yours truly,

December 21st, 1904.

HENRY SEWELL.

THE LONDON HOSPITAL FUNDS, THE LONDON HOSPITAL AND Mr. STEPHEN COLERIDGE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Stephen Coleridge has forwarded to me, with his compliments a copy of your issue of December 21st. I am very grateful to him, and I congratulate you on having obtained so active and zealous a propagandist of your views.

I do not expect from you any too charitable a view of my conduct or motives. I have never received anything but hostile criticism from you ever since I have worked for hospitals. I may be wrong, and you

always right—quite likely. But you will allow me, I am sure, to reply to your criticisms in your leading article in that number.

In the first place you criticise me for taking upon myself the defence of a grant from a hospital "to its college"—that is a better way of describing this than "to its school," because the grant is not made towards the education of students, but in return for very valuable services rendered by the Professors of the college, and by the students, to the hospital. But let this pass. You criticise me for replying because I am "a subscriber to, and not an official of, the Sunday Fund." This is a little unfortunate, for I have been a member of the Council for many years.

I might not, however, have spoken at all, had not the Rev. Lionel Lewis made a very violent attack on the London Hospital because we, as he puts it, spent £7,000 on a cricket ground, while his poor people were dying for want of hospital accommodation (his parish is in Hoxton not Whitechapel). He held me up to scorn as cruel, extravagant and unmindful of the crying needs of the sick poor.

Surely this is a little rough on a man, who, however wrong according to you in all his ways, at any rate may be supposed to care something for the sick poor; or else to be an idiot for devoting the best part of his leisure to hospital work. You have never suggested that I am quite an idiot, so I take it you will not go so far as to agree with this minister of the Gospel of Peace and Goodwill.

What are the facts—facts which I was driven by the above sneer to give, and facts which, when known to the rev. gentleman brought no apology from him. We bought, and spent on a cricket ground—£6,000, not £7,000. But before doing so we had made an agreement to let it on lease at 4 per cent. on our expenditure to a very prosperous Club, composed of all our students (£2 2s. a year subscription). They asked us to lend them the money at this rate on the security of the ground. But we were very strongly advised by experts to purchase the freehold ourselves. And their advice has been right. To-day we could sell the ground for far more than the £6,000.

You write "the point was whether the hospital had any right to invest charitable funds in the purchase of a cricket ground." Why not? if it pays as much as in a ground lease or leases, or land round the hospital, or in Consols—an investment, by the bye, in which a hospital can lose a good deal, as I know to my cost.

How very unfair also is your remark that "Mr. Holland was silent when asked if the accounts of the school were sent to every subscriber." It is difficult to believe that your reporter did not hear my reply. I was challenged on the point, and gave a direct answer, not in the middle of my speech, but a direct answer to the Lord Mayor, that every subscriber to the hospital could have a copy of the College accounts which are printed, and audited by a chartered accountant.

Attack me as much as seemeth good unto your circulation. But play fair, and do not show any personal animosity in controversial criticism.

I am, Sir, yours truly.

SYDNEY HOLLAND.

December 24th, 1904.

[Our personal respect for Mr. Holland's good faith and honourable intention has often been warmly expressed. At the same time, we have been obliged to differ from him at times. In the present instance, a point of vital importance is involved, namely, the diversion of funds subscribed for purely hospital purposes. The £6,000 was devoted to the purchase of a "sports" ground, not as a hospital endowment investment. Mr. Holland must give us the same credit for fairness of purpose that he claims for himself. We shall afford him every opportunity of a full statement and discussion in these columns. Mr. Coleridge is also entitled to full expression, however unhesitatingly we may condemn his anti-vivisection tactics.—ED. M.P. & C.]

## Medical News.

### Poisoned by Gelsemium.

At the assizes at Leeds on December 10th, a grocer was charged with the manslaughter of a girl. The story as it stands seems highly improbable, for it runs that the girl went to the shop to purchase fuller's earth. The grocer said he did not keep it but advised her to try witch-hazel. In mistake he sold her gelsemium and the girl died shortly after taking it. Mr. Justice Darling said there was no evidence of criminal negligence and the jury by his advice, returned a verdict of not guilty.

### Prosecution of an Unregistered Dentist.

At the Cardigan police court on December 12th, a man was fined 20s. and costs for falsely taking and using the name of a dentist without being registered in accordance with the provisions of the Dentists Act, 1878. He stated, in defence that he had a certificate of proficiency from an American college.

### New Regulations of the Royal University of Ireland.

THE Royal University of Ireland has issued the following new regulations in reference to the final M.B. examinations:—(1) In the spring and again in the autumn of each year two separate examinations will be held simultaneously, one for pass candidates only, the other for honour candidates only. When entering each candidate must state at which of these examinations he elects to be examined. A candidate who has entered for the honour examination may be allowed to change to the pass examination on giving to the secretaries a satisfactory reason for doing so at least one week before the commencement of the examination; but under no circumstances will a candidate who has entered for the pass examination be allowed to change to the honour examination. (2) Honour exhibitions will be awarded on the results of the honour examination only. (3) Candidates at the honour examination whose answering may not be such as to qualify them for honours may nevertheless be adjusted to have passed the examination provided they exhibit in their answers knowledge equivalent to what is required from candidates who satisfy the examiners at the pass examination.

### University of Oxford.

IN a congregation held on December 17th, the last day of Michaelmas term, presided over by the Vice-Chancellor (Dr. Merry, Rector of Lincoln College), the following degrees were conferred:—

M.D.—H. P. Cholmeley and E. Mallam, Magdalen.

M.B. and B.Ch.: E. Burstal, Trinity; R. A. Chisolm, Wadham; and H. R. Dean, Magdalen.

D.Sc.: T. C. Porter, Exeter; and H. B. Baker, Christ Church.

*Final Examination.*—Medicine, Surgery, and Midwifery: A. W. Brodribb, University College; E. Burstal, Trinity; R. A. Chisolm, Wadham; H. R. Dean, Magdalen; H. Frankish, Worcester; J. Freeman, University College; A. H. Hogarth, and R. H. Sankey, Christ Church; C. J. Singer, Magdalen; E. Mc.L. Smith, Queen's; P. F. Tinné, Magdalen; and J. A. Vlasto, New.

### Royal College of Physicians of Edinburgh.

At a recent meeting of the Royal College of Physicians of Edinburgh, Dr. John Playfair was elected President of the College; Dr. Thomas S. Coulston, Vice-President; and Sir Thomas R. Fraser, Sir John Batty Tuke, Dr. Charles E. Underhill, Dr. James Ritchie, and Dr. R. W. Philip were elected to the Council with the President and Vice-President.

### Trinity College, Dublin.

*Michaelmas Term, 1904:*—The following candidates passed the Final Examination in Surgery: Eva J. Jellett, Hugh Stewart, William Hassard, Thomas Creaser, Robertson S. Smyth, John Cunningham, Richard Kelly and Arthur A. M'Neight (equal), Charles E. Fawcett, Thomas J. T. Wilmot, Thomas Wilson, Gerrard A. Crowley, Keith R. C. Hallows, William J. M'IVOR.
